About the Cloudera ODBC Connector for Apache Impala

The Cloudera ODBC Connector for Apache Impala is used for direct SQL and Impala SQL access to Apache Hadoop / Impala distributions, enabling Business Intelligence (BI), analytics, and reporting on Hadoop / Impala-based data. The connector efficiently transforms an application's SQL query into the equivalent form in Impala SQL, which is a subset of SQL-92. If an application is Impala-aware, then the connector is configurable to pass the query through to the database for processing. The connector interrogates Impala to obtain schema information to present to a SQL-based application. Queries, including joins, are translated from SQL to Impala SQL. For more information about the differences between Impala SQL and SQL, see Features.

The Cloudera ODBC Connector for Apache Impala complies with the ODBC 3.80 data standard and adds important functionality such as Unicode and 32- and 64-bit support for high-performance computing environments.

ODBC is one of the most established and widely supported APIs for connecting to and working with databases. At the heart of the technology is the ODBC connector, which connects an application to the database. For more information about ODBC, see: https://insightsoftware.com/blog/what-is-odbc/. For complete information about the ODBC specification, see the ODBC API Reference from the Microsoft documentation: https://docs.microsoft.com/en-us/sql/odbc/reference/syntax/odbc-api-reference.

Note: The AIX and Solaris connectors are not available through the Cloudera website. To get these connectors, contact the Sales & Solutions team:

Phone number: +1.604.633.0008 ext 2

Email: solutions@simba.com

Note: This is the most up-to-date version of the Installation and Configuration Guide, for use with version 2.8 of the connector. If you are using an older version of the connector, certain features may not be available and certain settings may behave in unexpected ways. Please consult the PDF version of the Installation and Configuration Guide that was installed with your connector.

The Installation and Configuration Guide is suitable for users who are looking to access data residing within Impala from their desktop environment. Application developers might also find the information helpful. Refer to your application for details on connecting via ODBC.

Note: For basic configuration instructions that allow you to quickly set up the Windows connector so that you can evaluate and use it, see the Simba ODBC Connectors Quick Start Guide for Windows. The Quick Start Guide also explains how to use the connector in various applications.

Windows Connector

This section provides an overview of the Connector in the Windows platform, outlining the required system specifications and the steps for installing and configuring the connector in Windows environments.

Windows System Requirements

The Cloudera ODBC Connector for Apache Impala is expected to be compatible with all supported CDP and CDW versions.

Install the connector on client machines where the application is installed. Before installing the connector, make sure that you have the following:

- Administrator rights on your machine.
- A machine that meets the following system requirements:
 - One of the following operating systems:
 - Windows 11 or 10
 - Windows Server 2022, 2019, 2016
 - 100 MB of available disk space
 - Visual C++ Redistributable for Visual Studio 2022 installed (with the same bitness as the connector that you are installing).

You can download the installation packages at https://learn.microsoft.com/enus/cpp/windows/latest-supported-vc-redist?view=msvc-170

Installing the Connector in Windows

On 64-bit Windows operating systems, you can execute both 32-bit and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use a connector whose bitness matches the bitness of the client application:

- ClouderaImpalaODBC32.msi for 32-bit applications
- ClouderaImpalaODBC64.msi for 64-bit applications

You can install both versions of the connector on the same machine.

To install the Cloudera ODBC Connector for Apache Impala in Windows:

- 1. Depending on the bitness of your client application, double-click to run ClouderalmpalaODBC32.msi or ClouderalmpalaODBC64.msi.
- 2. Click Next.
- 3. Select the check box to accept the terms of the License Agreement if you agree, and then click Next.
- 4. To change the installation location, click Change, then browse to the desired folder, and then click OK. To accept the installation location, click Next.

- 5. Click Install.
- 6. When the installation completes, click **Finish**.

Uninstalling the Connector in Windows

You can uninstall the Cloudera ODBC Connector for Apache Impala in Windows by running the Installer Package.

To uninstall the Cloudera ODBC Connector for Apache Impala in Windows:

- Double-click to run ClouderalmpalaODBC32-bit.msi or ClouderalmpalaODBC64-bit.msi
- 2. Click Next.
- Click Remove.
- 4. When the wizard completes uninstalling, click **Finish**.

Creating a Data Source Name in Windows

Typically, after installing the Cloudera ODBC Connector for Apache Impala, you need to create a Data Source Name (DSN). A DSN is a data structure that stores connection information so that it can be used by the connector to connect to Impala.

Alternatively, you can specify connection settings in a connection string or as connector-wide settings. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

The following instructions describe how to create a DSN. For information about specifying settings in a connection string, see Using a Connection String. For information about connector-wide settings, see Setting Connector-Wide Configuration Options in Windows.

To create a Data Source Name in Windows:

1. From the Start menu, go to ODBC Data Sources.

Note: Make sure to select the ODBC Data Source Administrator that has the same bitness as the client application that you are using to connect to Impala.

- 2. In the ODBC Data Source Administrator, click the Drivers tab, and then scroll down as needed to confirm that the Cloudera ODBC Connector for Apache Impalaappears in the alphabetical list of ODBC connectors that are installed on your system.
- 3. Choose one:
 - To create a DSN that only the user currently logged into Windows can use, click the User DSN tab.

Or, to create a DSN that all users who log into Windows can use, click the System DSN tab.

Note: It is recommended that you create a System DSN instead of a User DSN. Some applications load the data using a different user account, and might not be able to detect User DSNs that are created under another user account.

- 4. Click Add.
- 5. In the Create New Data Source dialog box, select Cloudera ODBC Connector for Apache Impala and then click Finish. The Cloudera ODBC Connector for Apache ImpalaDSN Setup dialog box opens.
- 6. In the **Data Source Name** field, type a name for your DSN.
- 7. Optionally, in the **Description** field, type relevant details about the DSN.
- 8. In the Host field, type the IP address or host name of the network load balancer (NLB) or one of the Impala nodes if you are deployed without an NLB.
- 9. In the Port field, type the number of the TCP port that the Impala server uses to listen for client connections.
 - Note: The default port number used by Impala is 21050.
- 10. In the **Database** field, type the name of the database schema to use when a schema is not explicitly specified in a query.

Note: You can still issue queries on other schemas by explicitly specifying the schema in the query. To inspect your databases and determine the appropriate schema to use, type the show databases command at the Impala command prompt.

11. In the Authentication area, configure authentication as needed. For more information, see Configuring Authentication in Windows.

Note:

The default configuration of Impala requires the Cloudera ODBC Connector for Apache Impala to be configured to use the No Authentication mechanism.

- 12. Optionally, if the operations against Impala are to be done on behalf of a user that is different than the authenticated user for the connection, type the name of the user to be delegated in the Delegation UID field.
- 13. In the **Transport Mode** drop-down list, select the Thrift transport protocol to use in the Thrift layer.
- Note: For information about how to determine which Thrift transport protocols your Impala server supports, see Authentication Options.
- 14. To configure a connection through a proxy server, click Proxy Options. For more information, see Configuring a Proxy Connection in Windows.

- 15. If the Transport Mode option is set to HTTP, then to configure HTTP options such as custom headers, click **HTTP Options**. For more information, see Configuring HTTP Options in Windows.
- To configure client-server verification over SSL, click SSL Options. For more information, see Configuring SSL Verification in Windows.
- To configure advanced connector options, click Advanced Options. For more information, see Configuring Advanced Options in Windows.
- To configure server-side properties, click Advanced Options and then click Server Side Properties. For more information, see Configuring Server-Side Properties in Windows.
- To configure logging behavior for the connector, click Logging Options. For more information, see Configuring Logging Options in Windows.
- To test the connection, click Test. Review the results as needed, and then click OK.

Note: If the connection fails, then confirm that the settings in the Cloudera ODBC Connector for Apache Impala DSN Setup dialog box are correct. Contact your Impala server administrator as needed.

- 21. To save your settings and close the Cloudera ODBC Connector for Apache Impala DSN Setup dialog box, click **OK**.
- 22. To close the ODBC Data Source Administrator, click **OK**.

Configuring Authentication in Windows

Some Impala servers are configured to require authentication for access. To connect to an Impala server, you must configure the Cloudera ODBC Connector for Apache Impala to use the authentication mechanism that matches the access requirements of the server and provides the necessary credentials.

For information about how to determine the type of authentication your Impala server requires, see Authentication Options.

You can specify authentication settings in a DSN, in a connection string, or as connector-wide settings. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

The following authentication methods are available:

- Using No Authentication
- Using Kerberos
- Using Advanced Kerberos
- Using SAML 2.0
- Using SASL User Name
- Using JSON Web Token (JWT)

- Using User Name And Password
- Using OAuth 2.0

If cookie-based authentication is enabled in your Impala database, you can specify a list of authentication cookies in the HTTPAuthCookies connection property. In this case, the connector authenticates the connection once based on the provided authentication credentials. It then uses the cookie generated by the server for each subsequent request in the same connection. For more information, see HTTPAuthCookies.

Note:

in Windows, the HTTPAuthCookies property must be set in a connection string.

Using No Authentication

For this authentication mechanism, you do not need to configure any additional settings.

Note:

The default configuration of Impala requires the Cloudera ODBC Connector for Apache Impala to be configured to use the No Authentication mechanism.

To configure a connection without authentication:

- 1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click Configure.
- 2. From the **Mechanism** drop-down list, select **No Authentication**.
- 3. If the Impala server is configured to use SSL, then click SSL Options to configure SSL for the connection. For more information, see Configuring SSL Verification in Windows.
- 4. To save your settings and close the dialog box, click **OK**.

Using Kerberos

If the Use Only SSPI advanced option is disabled, then Kerberos must be installed and configured before you can use this authentication mechanism. For information about configuring Kerberos on your machine, see Configuring Kerberos Authentication for Windows. For information about setting the Use Only SSPI advanced option, see Configuring Advanced Options in Windows.

To configure Kerberos authentication:

- 1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click Configure.
- 2. From the **Mechanism** drop-down list, select **Kerberos**.

- 3. Choose one:
 - To use the default realm defined in your Kerberos setup, leave the Realm field empty.
 - Or, if your Kerberos setup does not define a default realm or if the realm of your Impala server
 host is not the default, then, in the Realm field, type the Kerberos realm of the Impala server.
- 4. In the Host FQDN field, type the fully qualified domain name of the Impala server host.

Note: To use the Impala server host name as the fully qualified domain name for Kerberos authentication, in the **Host FQDN** field, type **_HOST**.

- 5. In the **Service Name** field, type the service name of the Impala server.
- 6. Optionally, if you are using MIT Kerberos and a Kerberos realm is specified in the **Realm** field, then choose one:
 - To have the Kerberos layer canonicalize the server's service principal name, leave the Canonicalize Principal FQDN check box selected.
 - Or, to prevent the Kerberos layer from canonicalizing the server's service principal name, clear the Canonicalize Principal FQDN check box.
- 7. To allow the connector to pass your credentials directly to the server for use in authentication, select **Delegate Kerberos Credentials**.
- 8. If the Impala server is configured to use SSL, then click **SSL Options** to configure SSL for the connection. For more information, see Configuring SSL Verification in Windows.
- 9. Optionally, in the **Transport Buffer Size** field, type the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note:

In most circumstances, the default value of 1000 bytes is optimal.

10. To save your settings and close the dialog box, click **OK**.

Using Advanced Kerberos

The Advanced Kerberos authentication mechanism allows concurrent connections within the same process to use different Kerberos user principals.

This authentication mechanism is supported only when the connector is configured to handle Kerberos authentication using MIT Kerberos:

- MIT Kerberos must be installed on your machine.
- The Use Only SSPI option must be disabled. For more information, see Use Only SSPI.

When you use Advanced Kerberos authentication, you do not need to run the kinit command to obtain a Kerberos ticket. Instead, you use a JSON file to map your Impala user name to a Kerberos user principal name and a keytab that contains the corresponding keys. The connector obtains Kerberos

tickets based on the specified mapping. As a fallback, you can specify a keytab that the connector uses by default if the mapping file is not available or if no matching keytab can be found in the mapping file.

Note:

- For information about the schema of the mapping file and how the connector handles invalid mappings, see UPN Keytab Mapping File.
- For information about how the connector searches for a keytab file if the keytab mapping and default keytab file are invalid, see Default Keytab File.

To configure Advanced Kerberos authentication:

- 1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
- 2. In the **Mechanism** drop-down list, select **Kerberos**.
- Choose one:
- To use the default realm defined in your Kerberos setup, leave the Realm field empty.
- Or, if your Kerberos setup does not define a default realm or if the realm of your Impala server host is not the default, then, in the **Realm** field, type the Kerberos realm of the Impala server.
- 4. In the Host FQDN field, type the fully qualified domain name of the Impala server host.
- Note:

To use the Impala server host name as the fully qualified domain name for Kerberos authentication, in the Host FQDN field, type _HOST.

- 5. In the **Service Name** field, type the service name of the Impala server.
- 6. Optionally, if you are using MIT Kerberos and a Kerberos realm is specified in the Realm field, then choose one:
- To have the Kerberos layer canonicalize the server's service principal name, leave the Canonicalize Principal FQDN check box selected.
- Or, to prevent the Kerberos layer from canonicalizing the server's service principal name, clear the Canonicalize Principal FQDN check box.
- 7. Select the **Use Keytab** check box.

Note:

If the check box is not available, make sure that MIT Kerberos is installed on your machine.

8. In the **User Name** field, type an appropriate user name for accessing the Impala server.

- 9. Click **Keytab Options** and then do the following in the Keytab Options dialog box:
 - a. In the **UPN Keytab Mapping File** field, specify the full path to a JSON file that maps your Impala user name to a Kerberos user principal name and a keytab file.
 - b. In the **Default Keytab File** field, specify the full path to a keytab file that the connector can use if the mapping file is not available or if no matching keytab can be found in the mapping file.
 - c. To save your settings and close the dialog box, click **OK**.
- If the Impala server is configured to use SSL, then click SSL Options to configure SSL for the connection. For more information, see Configuring SSL Verification in Windows.
- Optionally, in the Transport Buffer Size field, type the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note:

In most circumstances, the default value of 1000 bytes is optimal.

12. To save your settings and close the dialog box, click **OK**.

Using SAML 2.0

This authentication mechanism enables you to authenticate via Single Sign-On using SAML 2.0 against supported servers.

Important: In order to use SAML 2.0 for authentication, Transport Mode must be set to HTTP and SSL must be enabled.

To configure SAML 2.0 authentication:

- 1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
- 2. In the Mechanism drop-down list, select SAML_2.0.
- 3. In the **Host** field, type the fully qualified domain name of the Impala server host.
- 4. In the **Port** field, type the number of the TCP port that the Impala server uses to listen for client connections.
- Optionally, in the Transport Buffer Size field, type the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note: In most circumstances, the default value of 1000 bytes is optimal.

- 6. In the **Transport Mode** drop-down list, select **HTTP**.
- 7. Optionally, click **SAML Options** and select the **Ignore SQL_DRIVER_NOPROMPT** check box. When the application is making a SQLDriverConnect call with a SQL_DRIVER_NOPROMPT flag, this option displays the web browser used to complete the browser based authentication flow.

- 8. Optionally, click SAML Options and select the Enable Auth Cookie Caching check box. When establishing a new connection using SAML SSO authentication, the connector caches the authorization cookie and does not repeatedly open a new browser.
- 9. Optionally, click SAML Options, and select the Enable Routing To Same Coordinator check box. It is active only when the Enable Auth Cookie Caching check box is already selected. The connector uses the cached SAML auth cookie to route to the same coordinator in subsequent connections. For more information, see the configuration option Enable Routing To Same Coordinator For Cached SAML Auth Cookie.
- 10. Click HTTP Options and in the HTTP Path field, type the partial URL corresponding to the Impala server. For more information, see Configuring HTTP Options in Windows.
- 11. Click SSL Options and select the Enable SSL check box. For more information, see Configuring SSL Verification in Windows
- 12. To save your settings and close the dialog box, click **OK**.

Note:

Tableau does not currently support SAML 2.0 in the UI. To use SAML 2.0 with the Tableau application:

In the registry, HKEY LOCAL MACHINE\SOFTWARE\Cloudera\Cloudera ODBC Driver for Impala\Driver, add the following connector-wide configurations:

DriverConfigTakePrecedence=1, AuthMech=SAML 2.0; TransportMode=http; SSOIgnoreDriverNoPrompt=1

After adding the above settings in the registry, all the connections with the Cloudera ODBC Connector for Apache Impala on this machine will use SAML 2.0 authentication.

Using SASL User Name

This authentication mechanism requires a user name but not a password. The user name labels the session, facilitating database tracking.

To configure SASL User Name authentication:

- 1. To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click Configure.
- 2. From the **Mechanism** drop-down list, select **SASL User Name**.
- 3. In the User Name field, type an appropriate user name for accessing the Impala server.
- 4. Optionally, in the Transport Buffer Size field, type the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note: In most circumstances, the default value of 1000 bytes is optimal.

5. To save your settings and close the dialog box, click **OK**.

Using JSON Web Token (JWT)

This authentication mechanism enables you to authenticate via JSON Web Token against supported servers.

To configure JWT authentication:

- To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
- 2. From the **Mechanism** drop-down list, select **JWT**.
- 3. In the **JWT String** field, type a valid jwt string for accessing the Impala server.
- 4. To encrypt your credentials, click **Encryption Options** and then select one of the following:
 - . If the credentials are used only by the current Windows user, select Current User Only.
 - Or, if the credentials are used by all users on the current Windows machine, select All Users
 Of This Machine.

To confirm your choice and close the Encryption Options dialog box, click OK.

5. To save your settings and close the dialog box, click **OK**.

Important:

In order to use JWT for authentication, TransportMode must be set to HTTP and JWTString must be specified in the connection string.

Using User Name And Password

This authentication mechanism requires a user name and a password.

Note: This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled.

To configure User Name And Password authentication:

- To access authentication options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click Configure.
- 2. From the **Mechanism** drop-down list, select **User Name And Password**.
- 3. In the **User Name** field, type an appropriate user name for accessing the Impala server.
- 4. In the Password field, type the password corresponding to the user name you typed above.
- 5. To encrypt your credentials, click **Password Options** and then select one of the following:
 - If the credentials are used only by the current Windows user, select Current User Only.
 - Or, if the credentials are used by all users on the current Windows machine, select All Users
 Of This Machine.

To confirm your choice and close the Password Options dialog box, click OK.

- 6. If the Impala server is configured to use SSL, then click SSL Options to configure SSL for the connection. For more information, see Configuring SSL Verification in Windows.
- 7. Optionally, in the **Transport Buffer Size** field, type the number of bytes to reserve in memory for buffering unencrypted data from the network.
 - Note: In most circumstances, the default value of 1000 bytes is optimal.
- 8. Optionally, to use SASL to handle authentication, select the Use Simple Authentication and Security Layer (SASL) check box.
 - Note: If the Transport Mode property is specified, it takes precedence over this property.
- 9. To save your settings and close the dialog box, click **OK**.

Using OAuth 2.0

Three types of authentication work flow are available when using OAuth 2.0, token pass-through, client credentials, or browser based authentication.

When you use OAuth 2.0 authentication, HTTP is the only transport mode protocol available.

Token Pass-through

This authentication mechanism requires a valid OAuth 2.0 access token. Be aware that access tokens typically expire after a certain amount of time, after which you must either refresh the token or obtain a new one from the server. To obtain a new access token, see Using OAuth 2.0.

To configure OAuth 2.0 token pass-though authentication:

- 1. To access authentication options for a DSN, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click Configure
- 2. From the **Mechanism** drop-down list, select **OAuth 2.0**.
- 3. Click **OAuth Options**, and then do the following:
 - a. From the Authentication Flow drop-down list, select Token Passthrough.
 - b. In the **Access Token** field, type your access token.
 - c. Optionally, select Token or Client Secret Encryption Options and choose the encryption password for Current User Only or All Users of this Machine. Click OK.
 - d. To save your settings and close the OAuth Options dialog box, click **OK**.
- 4. To save your settings and close the DSN Setup dialog box or the Driver Configuration tool, click OK.

Providing a New Access Token

Once an access token expires, you can provide a new access token for the connector.

Note: When an access token expires, the connector returns a "SQLState 08006" error.

To obtain a new access token:

- 1. In the connection string, set the Auth AccessToken property with a new access token.
- 2. Call the SQLSetConnectAttr function with SQL_ATTR_CREDENTIALS (122) as the attribute and the new connection string as the value. The connector will update the current connection string with the new access token.

Note: Calling the SQLGetConnectAttr function with SQL_ATTR_CREDENTIALS (122) returns the entire connection string used during connection.

- 3. Call the SQLSetConnectAttr function with SQL_ATTR_REFRESH_CONNECTION (123) as the attribute and SQL_REFRESH_NOW (-1) as the value. This signals the connector to update the access token value.
- 4. Retry the previous ODBC API call. After obtaining the new access token, the open connection, statements, and cursors associated with it remain valid for use.

Client Credentials

This authentication mechanism requires SSL to be enabled.

You can use client secret as the client credentials.

To configure OAuth 2.0 client credentials authentication using the client secret:

- 1. To access authentication options for a DSN, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.
- 2. From the **Mechanism** drop-down list, select **OAuth 2.0**.
- 3. Click **OAuth Options**, and then do the following:
 - a. From the Authentication Flow drop-down list, select Client Credentials.
 - b. In the **Client ID** field, type your client ID.
 - c. In the Client Secret field, type your client secret.
 - d. In the **Audience** field, type your OAuth audience.
 - e. In the **Token Endpoint** field, type your OAuth token endpoint.
 - f. Optionally, select **Token** or **Client Secret Encryption Options** and choose the encryption password for **Current User Only** or **All Users of this Machine**. Click **OK**.
 - g. Optionally, in the **Scope** field, type your OAuth scope.
 - h. To save your settings and close the OAuth Options dialog box, click OK.
- To save your settings and close the DSN Setup dialog box or the Driver Configuration tool, click OK.

Browser Based

This authentication mechanism requires SSL to be enabled.

To configure OAuth 2.0 browser based authentication:

1. To access authentication options for a DSN, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, and then click **Configure**.

- 2. From the **Mechanism** drop-down list, select **OAuth 2.0**.
- 3. Click **OAuth Options**, and then do the following:
 - a. From the Authentication Flow drop-down list, select Browser Based Authorization Code.
 - b. In the **Client ID** field, type your client ID.
 - c. In the **Client Secret** field, type your client secret.
 - d. Optionally, select Token or Client Secret Encryption Options and choose the encryption password for Current User Only or All Users of this Machine. Click OK.
 - e. In the **Audience** field, type your OAuth audience.
 - f. In the **Token Endpoint** field, type your OAuth token endpoint.
 - g. In the Authorization Endpoint field, type your OAuth authorization endpoint.
 - h. Optionally, in the **Scope** field, type your OAuth scope.
 - i. Optionally, select the Ignore SQL_DRIVER_NOPROMPT check box. When the application is making a SQLDriverConnect call with a SQL_DRIVER_NOPROMPT flag, this option displays the web browser used to complete the browser based authentication flow.
 - j. To save your settings and close the OAuth Options dialog box, click **OK**.
- 4. To save your settings and close the DSN Setup dialog box or the Driver Configuration tool, click OK.

Note: When the browser based authentication flow completes, the access token and refresh token are saved in the token cache and the connector does not need to authenticate again. For more information, see Enable Token Cache.

Configuring a Proxy Connection in Windows

If you are connecting to the data source through a proxy server, you must provide connection information for the proxy server.

To configure a proxy server connection in Windows:

- 1. To access proxy server options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Proxy Options**.
- 2. Select the **Use Proxy** check box.
- 3. In the **Proxy Host** field, type the host name or IP address of the proxy server.
- 4. In the Proxy Port field, type the number of the TCP port that the proxy server uses to listen for client connections.
- 5. In the **Proxy Username** field, type your user name for accessing the proxy server.
- 6. In the **Proxy Password** field, type the password corresponding to the user name.
- 7. To encrypt your credentials, click **Password Options** and then select one of the following:

- If the credentials are used only by the current Windows user, select Current User Only.
- Or, if the credentials are used by all users on the current Windows machine, select All Users
 Of This Machine.

To confirm your choice and close the Password Options dialog box, click **OK**.

8. To save your settings and close the HTTP Proxy Options dialog box, click OK.

Configuring HTTP Options in Windows

You can configure options such as custom headers when using the HTTP transport protocol in the Thrift layer. For information about how to determine if your Impala server supports the HTTP transport protocol, see Authentication Options.

The following instructions describe how to configure HTTP options in a DSN. You can specify the connection settings described below in a DSN, in a connection string, or as connector-wide settings. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To configure HTTP options in Windows:

- 1. Open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then make sure that the Transport Mode option is set to **HTTP**.
- 2. To access HTTP options, click HTTP Options.

Note: The HTTP options are available only when the Transport Mode option is set to HTTP

- 3. In the HTTP Path field, type the partial URL corresponding to the Impala server.
- To create a custom HTTP header, click Add, then type appropriate values in the Key and Value fields, and then click OK.
- 5. To edit a custom HTTP header, select the header from the list, then click **Edit**, then update the **Key** and **Value** fields as needed, and then click **OK**.
- 6. To delete a custom HTTP header, select the header from the list, and then click **Remove**. In the confirmation dialog box, click **Yes**.
- 7. To save your settings and close the HTTP Properties dialog box, click **OK**.

Configuring SSL Verification in Windows

If you are connecting to an Impala server that has Secure Sockets Layer (SSL) enabled, you can configure the connector to connect to an SSL-enabled socket. When using SSL to connect to a server, the connector can be configured to verify the identity of the server.

The following instructions describe how to configure SSL in a DSN. You can specify the connection settings described below in a DSN, in a connection string, or as connector-wide settings. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

Important:

If Check Certificate Revocation is enabled, make sure that the connector has access to the CRL/OCSP server. When using a proxy between the connector and the CRL/OCSP server, make sure that the proxy is properly configured.

If the proxy uses LDAP authentication, save the proxy credential to the Windows system. This is because the connector does not display a credential dialog when checking the revocation. Therefore, if the credential is not saved, the connector does not check revocation and returns an SSL error.

To configure SSL verification in Windows:

- 1. To access SSL options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **SSL Options**.
- 2. Select the **Enable SSL** check box.
- 3. To allow authentication using self-signed certificates that have not been added to the list of trusted certificates, select the Allow Self-signed Server Certificate check box.
- 4. To allow the common name of a CA-issued SSL certificate to not match the host name of the Impala server, select the Allow Common Name Host Name Mismatch check box.
- 5. To specify the CA certificates that you want to use to verify the server, do one of the following:
 - To verify the server using the trusted CA certificates from a specific .pem file, specify the full path to the file in the Trusted Certificates field and clear the Use System Trust Store check box.
 - Or, to use the trusted CA certificates . pem file that is installed with the connector, leave the Trusted Certificates field empty, and clear the Use System Trust Store check box.
 - Or, to use the Windows trust store, select the Use System Trust Store check box.

Important:

- If you are using the Windows trust store, make sure to import the trusted CA certificates into the trust store.
- If the trusted CA supports certificate revocation, select the Check Certificate Revocation check box.
- 6. From the Minimum TLS Version drop-down list, select the minimum version of TLS to use when connecting to your data store.
- 7. To save your settings and close the SSL Options dialog box, click **OK**.

Configuring Advanced Options in Windows

You can configure advanced options to modify the behavior of the connector.

The following instructions describe how to configure advanced options in a DSN. You can specify the connection settings described below in a DSN, in a connection string, or as connector-wide settings.

Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To configure advanced options in Windows:

- 1. To access advanced options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click **Configure**, and then click **Advanced Options**.
- 2. To disable translation from ODBC SQL to Impala SQL, select the Use Native Query check box.

Important:

- When this option is enabled, the connector cannot execute parameterized queries.
- By default, the connector applies transformations to the queries emitted by an application to convert the queries into an equivalent form in Impala SQL. If the application is Impala-aware and already emits Impala SQL, then turning off the translation avoids the additional overhead of query transformation.
- 3. To enable the connector to successfully run queries that contain transaction statements, select the **Ignore Transactions** check box.

Note: The transaction statements are not executed, because ODBC does not support them. Enabling this option allows the connector to run the query without returning error messages.

- To enable the connector to return SQL_WVARCHAR instead of SQL_VARCHAR for STRING and VARCHAR columns, and SQL_WCHAR instead of SQL_CHAR for CHAR columns, select the Use SQL Unicode Types check box.
- 5. To have the connector automatically attempt to reconnect to the server if communications are lost, select **Enable Auto Reconnect**.
- 6. To have the connector restrict catalog queries to the current schema when no schema is specified, or when the schema is specified with the wildcard character %, select **Restrict Metadata with Current Schema**.
- 7. In the Rows Fetched Per Block field, type the number of rows to be fetched per block.
- 8. In the **Socket Timeout** field, type the number of seconds that the TCP socket waits for a response from the server before timing out the request and returning an error message.

Note:

Setting the Socket Timeout value to 0 disables the timeout feature.

- 9. In the **String Column Length** field, type the maximum data length for STRING columns.
- 10. In the **Async Exec Poll Interval** field, type the time in milliseconds between each poll for the query execution status.
- 11. To handle Kerberos authentication using the SSPI plugin instead of MIT Kerberos by default, select one or both of the check boxes under the **Use Only SSPI** option:

- To configure the current DSN to use the SSPI plugin by default, select **Enable For This DSN**.
- To configure all DSN-less connections to use the SSPI plugin by default, select Enable For DSNless Connections.
- To configure all connections that use the Cloudera ODBC Connector for Apache Impala to use the SSPI plugin by default, select both check boxes.
- 12. Optionally, if you want the connector to retry queries that fail, select the Enable Query Retry check box and then do the following:
 - a. In the Max Retries field, type the maximum number of times that the connector retries each query.
 - b. In the Result Set Cache Size field, type the maximum amount of memory that the result set cache can occupy. Values must be specified in: B (bytes), KB (kilobytes), MB (megabytes), or GB (gigabytes).
 - c. In the Retry Interval field, type the amount of time that the connector waits between query retry attempts. Values must be specified in S (seconds) or MS (milliseconds).
- 13. To save your settings and close the Advanced Options dialog box, click OK.

Configuring Server-Side Properties in Windows

When connecting to a server that is running Impala 2.0 or later, you can use the connector to apply configuration properties to the server.

Important:

This feature is not supported for earlier versions of Impala, where the SET statement can only be executed from within the Impala shell.

The following instructions describe how to configure server-side properties in a DSN. You can specify the connection settings described below in a DSN, in a connection string, or as connector-wide settings. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To configure server-side properties in Windows:

- 1. To configure server-side properties, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click Configure, then click Advanced Options, and then click Server Side Properties.
- 2. To create a server-side property, click Add, then type appropriate values in the Key and Value fields, and then click OK. For example, to set the value of the MEM LIMIT query option to 1 GB, type MEM_LIMIT in the Key field and then type 100000000 in the Value field.
- 3. To edit a server-side property, select the property from the list, then click Edit, then update the Key and Value fields as needed, and then click OK.
- 4. To delete a server-side property, select the property from the list, and then click **Remove**. In the confirmation dialog box, click Yes.
- 5. To configure the connector to convert server-side property key names to all lower-case characters,

select the Convert Key Name To Lower Case check box.

6. To save your settings and close the Server Side Properties dialog box, click **OK**.

Configuring Logging Options in Windows

To help troubleshoot issues, you can enable logging. In addition to functionality provided in the Cloudera Cloudera ODBC Connector for Apache Impala, the ODBC Data Source Administrator provides tracing functionality.

Important: Only enable logging or tracing long enough to capture an issue. Logging or tracing decreases performance and can consume a large quantity of disk space.

Configuring Connector-wide Logging Options

The settings for logging apply to every connection that uses the Cloudera ODBC Connector for Apache Impala, so make sure to disable the feature after you are done using it. To configure logging for the current connection, see Configuring Logging for the Current Connection.

To enable connector-wide logging in Windows:

- To access logging options, open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click Configure, and then click Logging Options.
- 2. From the **Log Level** drop-down list, select the logging level corresponding to the amount of information that you want to include in log files:

Logging Level	Description
OFF	Disables all logging.
FATAL	Logs severe error events that lead the connector to abort.
ERROR	Logs error events that might allow the connector to continue running.
WARNING	Logs events that might result in an error if action is not taken.
INFO	Logs general information that describes the progress of the connector.
DEBUG	Logs detailed information that is useful for debugging the connector.
TRACE	Logs all connector activity.

- 3. In the Log Path field, specify the full path to the folder where you want to save log files.
- 4. If requested by Technical Support, type the name of the component for which to log messages in the **Log Namespace** field. Otherwise, do not type a value in the field.
- 5. In the Max Number Files field, type the maximum number of log files to keep.

Note: After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.

6. In the Max File Size field, type the maximum size of each log file in megabytes (MB).

Note: After the maximum file size is reached, the connector creates a new file and continues logging.

- 7. Click OK.
- 8. Restart your ODBC application to make sure that the new settings take effect.

The Cloudera ODBC Connector for Apache Impala produces the following log files at the location you specify in the Log Path field:

- A clouderaodbcdriverforimpala.log file that logs connector activity that is not specific to a connection.
- A clouderaodbcdriverforimpala connection [Number].log file for each connection made to the database, where [Number] is a number that identifies each log file. This file logs connector activity that is specific to the connection.

If you enable the UseLogPrefix connection property, the connector prefixes the log file name with the user name associated with the connection and the process ID of the application through which the connection is made. For more information, see UseLogPrefix.

To disable connector logging in Windows:

- 1. Open the ODBC Data Source Administrator where you created the DSN, then select the DSN, then click Configure, and then click Logging Options.
- 2. From the Log Level drop-down list, select LOG_OFF.
- 3. Click OK.
- 4. Restart your ODBC application to make sure that the new settings take effect.

Configuring Logging for the Current Connection

You can configure logging for the current connection by setting the logging configuration properties in the DSN or in a connection string. For information about the logging configuration properties, see Configuring Logging Options in Windows. Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

Note: If the LogLevel configuration property is passed in via the connection string or DSN, the rest of the logging configurations are read from the connection string or DSN and not from the existing connector-wide logging configuration.

To configure logging properties in the DSN, you must modify the Windows registry. For information about the Windows registry, see the Microsoft Windows documentation.

Important: Editing the Windows Registry incorrectly can potentially cause serious, systemwide problems that may require re-installing Windows to correct.

To add logging configurations to a DSN in Windows:

- 1. On the Start screen, type **regedit**, and then click the **regedit** search result.
- 2. Navigate to the appropriate registry key for the bitness of your connector and your machine:
 - 32-bit System DSNs: HKEY_LOCAL_ MACHINE\SOFTWARE\WOW6432Node\ODBC\ODBC.INI\[DSN Name]
 - 64-bit System DSNs: HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\[DSN Name]
 - 32-bit and 64-bit User DSNs: HKEY_CURRENT_USER\SOFTWARE\ODBC\ODBC.INI\
 [DSN Name]
- 3. For each configuration option that you want to configure for the current connection, create a value by doing the following:
 - a. If the key name value does not already exist, create it. Right-click the [DSN Name] and then select New > String Value, type the key name of the configuration option, and then press Enter.
 - b. Right-click the key name and then click Modify.
 - To confirm the key names for each configuration option, see Connector Configuration Options.
 - c. In the Edit String dialog box, in the **Value Data** field, type the value for the configuration option.
- 4. Close the Registry Editor.
- 5. Restart your ODBC application to make sure that the new settings take effect.

Setting Connector-Wide Configuration Options in Windows

When you specify connection settings in a DSN or connection string, those settings apply only when you connect to Impala using that particular DSN or string. As an alternative, you can specify settings that apply to every connection that uses the Cloudera ODBC Connector for Apache Impala by configuring them in the Windows Registry.

Note:

Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To set connector-wide configuration options in Windows:

- 1. Choose one:
- If you are using Windows 7 or earlier, click **Start**, then type **regedit** in the **Search** field, and then click **regedit.exe** in the search results.
- Or, if you are using Windows 8 or later, on the Start screen, type regedit, and then click the regedit search result.

- 2. Navigate to the appropriate registry key for the bitness of your connector and your machine:
- If you are using the 32-bit connector on a 64-bit machine, then browse to the following registry key:

HKEY LOCAL MACHINE\SOFTWARE\Wow6432Node\Cloudera\Cloudera ODBC Driver for Impala\Driver

Otherwise, browse to the following registry key:

HKEY_LOCAL_MACHINE\SOFTWARE\Cloudera\Cloudera ODBC Driver for Impala\Driver

- 3. For each connection property that you want to configure, do the following:
 - a. Right-click the **Driver** subkey and then select **New > String Value**.
 - b. Type the key name of the connection property, and then press **Enter**.

For example, to specify the authentication mechanism to use, type AuthMech. To verify the supported key name for each connector configuration option, refer to the "Key Name" column in the description of the option in Connector Configuration Options.

- c. Right-click the value that you created in the previous steps and then click **Modify**.
- d. In the Edit String dialog box, in the Value Data field, type the value that you want to set the connection property to and then click OK.

For example, to specify the Kerberos authentication mechanism, type 1.

4. Close the Registry Editor.

Configuring Kerberos Authentication for Windows **Active Directory**

The Cloudera ODBC Connector for Apache Impala supports Active Directory Kerberos in Windows. There are two prerequisites for using Active Directory Kerberos in Windows:

- MIT Kerberos is not installed on the client Windows machine.
- The MIT Kerberos Hadoop realm has been configured to trust the Active Directory realm, according to Apache's documentation, so that users in the Active Directory realm can access services in the MIT Kerberos Hadoop realm.

MIT Kerberos

Downloading and Installing MIT Kerberos for Windows 4.0.1

For information about Kerberos and download links for the installer, see the MIT Kerberos website: http://web.mit.edu/kerberos/.

To download and install MIT Kerberos for Windows 4.0.1:

- 1. Download the appropriate Kerberos installer:
 - For a 64-bit machine, use the following download link from the MIT Kerberos website: http://web.mit.edu/kerberos/dist/kfw/4.0/kfw-4.0.1-amd64.msi.
 - For a 32-bit machine, use the following download link from the MIT Kerberos website: http://web.mit.edu/kerberos/dist/kfw/4.0/kfw-4.0.1-i386.msi.

Note: The 64-bit installer includes both 32-bit and 64-bit libraries. The 32-bit installer includes 32-bit libraries only.

- 2. To run the installer, double-click the .msi file that you downloaded above.
- 3. Follow the instructions in the installer to complete the installation process.
- 4. When the installation completes, click **Finish**.

Setting Up the Kerberos Configuration File

Settings for Kerberos are specified through a configuration file. You can set up the configuration file as an .ini file in the default location, which is the C:\ProgramData\MIT\Kerberos5 directory, or as a .conf file in a custom location.

Normally, the C: $\ProgramData\MIT\Kerberos5$ directory is hidden. For information about viewing and using this hidden directory, refer to Microsoft Windows documentation.

Note: For more information on configuring Kerberos, refer to the MIT Kerberos documentation.

To set up the Kerberos configuration file in the default location:

- 1. Obtain a krb5.conf configuration file. You can obtain this file from your Kerberos administrator, or from the /etc/krb5.conf folder on the machine that is hosting the Impala server.
- 2. Rename the configuration file from krb5.conf to krb5.ini.
- 3. Copy the krb5.ini file to the C:\ProgramData\MIT\Kerberos5 directory and overwrite the empty sample file.

To set up the Kerberos configuration file in a custom location:

- 1. Obtain a krb5.conf configuration file. You can obtain this file from your Kerberos administrator, or from the /etc/krb5.conf folder on the machine that is hosting the Impala server.
- 2. Place the krb5.conf file in an accessible directory and make note of the full path name.
- 3. Open the System window:
 - Click Start , then right-click Computer, and then click Properties.
 - Or right-click This PC on the Start screen, and then click Properties.
- 4. Click Advanced System Settings.

- 5. In the System Properties dialog box, click the **Advanced** tab and then click **Environment Variables**.
- 6. In the Environment Variables dialog box, under the System Variables list, click New.
- 7. In the New System Variable dialog box, in the Variable Name field, type KRB5_CONFIG.
- 8. In the Variable Value field, type the full path to the krb5.conf file.
- 9. Click **OK** to save the new variable.
- 10. Make sure that the variable is listed in the System Variables list.
- 11. Click **OK** to close the Environment Variables dialog box, and then click **OK** to close the System Properties dialog box.

Setting Up the Kerberos Credential Cache File

Kerberos uses a credential cache to store and manage credentials.

To set up the Kerberos credential cache file:

- 1. Create a directory where you want to save the Kerberos credential cache file. For example, create a directory named C: \temp.
- 2. Open the System window:
 - Click Start , then right-click Computer, and then click Properties.
 - Or right-click This PC on the Start screen, and then click Properties.
- 3. Click Advanced System Settings.
- 4. In the System Properties dialog box, click the **Advanced** tab and then click **Environment Variables**.
- 5. In the Environment Variables dialog box, under the System Variables list, click New.
- 6. In the New System Variable dialog box, in the Variable Name field, type KRB5CCNAME.
- 7. In the Variable Value field, type the path to the folder you created above, and then append the file name krb5cache. For example, if you created the folder C: \temp, then type C:\temp\krb5cache.

Note: krb5cache is a file (not a directory) that is managed by the Kerberos software, and it should not be created by the user. If you receive a permission error when you first use Kerberos, make sure that the krb5cache file does not already exist as a file or a directory.

- 8. Click **OK** to save the new variable.
- 9. Make sure that the variable appears in the System Variables list.
- 10. Click OK to close the Environment Variables dialog box, and then click OK to close the System Properties dialog box.
- 11. To make sure that Kerberos uses the new settings, restart your machine.

Obtaining a Ticket for a Kerberos Principal

A principal refers to a user or service that can authenticate to Kerberos. To authenticate to Kerberos, a principal must obtain a ticket by using a password or a keytab file. You can specify a keytab file to use, or use the default keytab file of your Kerberos configuration.

To obtain a ticket for a Kerberos principal using a password:

- 1. Open MIT Kerberos Ticket Manager.
- 2. In MIT Kerberos Ticket Manager, click **Get Ticket**.
- 3. In the Get Ticket dialog box, type your principal name and password, and then click OK.

If the authentication succeeds, then your ticket information appears in MIT Kerberos Ticket Manager.

To obtain a ticket for a Kerberos principal using a keytab file:

- a. Open a command prompt:
 - Click Start , then click All Programs, then click Accessories, and then click Command Prompt.
 - Click the arrow button at the bottom of the Start screen, then find the Windows System program group, and then click Command Prompt.
- b. In the Command Prompt, type a command using the following syntax:

```
kinit -k -t [KeytabPath][Principal]
```

[KeytabPath] is the full path to the keytab file. For example:

C:\mykeytabs\myUser.keytab.

[Principal] is the Kerberos user principal to use for authentication. For example: myUser@EXAMPLE.COM.

c. If the cache location KRB5CCNAME is not set or used, then use the -c option of the kinit command to specify the location of the credential cache. In the command, the -c argument must appear last. For example:

```
kinit -k -t C:\mykeytabs\myUser.keytab myUser@EXAMPLE.COM -c
C:\ProgramData\MIT\krbcache
```

Krbcache is the Kerberos cache file, not a directory.

To obtain a ticket for a Kerberos principal using the default keytab file:

Note: For information about configuring a default keytab file for your Kerberos configuration, refer to the MIT Kerberos documentation.

- 1. Open a command prompt:
 - Click Start , then click All Programs, then click Accessories, and then click Command Prompt.
 - Click the arrow button at the bottom of the Start screen, then find the Windows System program group, and then click Command Prompt.
- 2. In the Command Prompt, type a command using the following syntax:

```
kinit -k [principal]
```

[principal] is the Kerberos user principal to use for authentication. For example: MyUser@EXAMPLE.COM.

3. If the cache location KRB5CCNAME is not set or used, then use the -c option of the kinit command to specify the location of the credential cache. In the command, the -c argument must appear last. For example:

```
kinit -k -t C:\mykeytabs\myUser.keytab myUser@EXAMPLE.COM -c
C:\ProgramData\MIT\krbcache
```

Krbcache is the Kerberos cache file, not a directory.

Verifying the Connector Version Number in Windows

If you need to verify the version of the Cloudera ODBC Connector for Apache Impala that is installed on your Windows machine, you can find the version number in the ODBC Data Source Administrator.

To verify the connector version number in Windows:

1. From the Start menu, go to **ODBC Data Sources**.

Note: Make sure to select the ODBC Data Source Administrator that has the same bitness as the client application that you are using to connect to Impala.

2. Click the **Drivers** tab and then find the Cloudera ODBC Connector for Apache Impala in the list of ODBC Connectors that are installed on your system. The version number is displayed in the Version column.

macOS Connector

This section provides an overview of the Connector in the mac OS platform, outlining the required system specifications and the steps for installing and configuring the connector in mac OS environments.

macOS System Requirements

The Cloudera ODBC Connector for Apache Impala is expected to be compatible with all supported CDP and CDW versions.

Install the connector on client machines where the application is installed. Each client machine that you install the connector on must meet the following minimum system requirements:

- One of the following macOS versions:
 - o macOS 11 (Universal Binary Intel and ARM support)
 - macOS 12 (Universal Binary Intel and ARM support)
 - macOS 13 (Universal Binary Intel and ARM support)
- 100MB of available disk space
- One of the following ODBC driver managers installed:
 - iODBC 3.52.9 or later
 - unixODBC 2.2.14 or later

Installing the Connector in macOS

The Cloudera ODBC Connector for Apache Impala is available for macOS as a .dmg file named ClouderaImpalaODBC.dmg. The connector supports both 32- and 64-bit client applications.

To install the Cloudera ODBC Connector for Apache Impala in macOS:

- 1. Double-click ClouderalmpalaODBC.dmg to mount the disk image.
- 2. Double-click ClouderalmpalaODBC.pkg to run the installer.
- 3. In the installer, click Continue.
- 4. On the Software License Agreement screen, click **Continue**, and when the prompt appears, click **Agree** if you agree to the terms of the License Agreement.
- 5. Optionally, to change the installation location, click **Change Install Location**, then select the desired location, and then click **Continue**.

Note: By default, the connector files are installed in the <code>/opt/cloudera/impalaodbc</code> directory.

- To accept the installation location and begin the installation, click Install.
- 7. When the installation completes, click **Close**.

Next, configure the environment variables on your machine to make sure that the ODBC Driver manager can work with the connector. For more information, Configuring the ODBC Driver Manager in Non-Windows Machines.

Uninstalling the Connector in macOS

You can uninstall the Cloudera ODBC Connector for Apache Impala in macOS by deleting the added files and folders from the Library.

To uninstall the Cloudera ODBC Connector for Apache Impala in macOS:

1. In the Finder, navigate to the location where the connector was installed.

Note: By default, the connector files are installed in the /opt/cloudera/impalaodbc directory.

- 2. Move all files and folders in this location to the Trash.
- 3. At the Terminal, run the following commands:
 - · To remove the installed connector: sudo rm -rf /opt/cloudera/impalaodbc
 - To remove the package receipts: sudo rm -rf /var/db/receipts/cloudera.impalaodbc.*
- 4. In the Finder, locate the odbcinst.ini file.
- 5. Remove the Cloudera ODBC Connector for Apache Impala stub by deleting this text:

Cloudera ODBC Data Connector for Impala= Installed

[Cloudera ODBC Data Connector for Impala]

Driver =

/opt/cloudera/impalaodbc/lib/universal/libclouderaimpalaodbc.dylib

Important: Make sure to delete the text corresponding to Cloudera ODBC Connector for Apache Impala for. If the wrong text is deleted, it may effect other connectors installed in the odbcinst.ini file.

Verifying the Connector Version Number in macOS

If you need to verify the version of the Cloudera ODBC Connector for Apache Impala that is installed on your macOS machine, you can query the version number through the Terminal.

To verify the connector version number in macOS:

macOS Connector

• At the Terminal, run the command:

```
pkgutil --info cloudera.impalaodbc
```

The command returns information about the Cloudera ODBC Connector for Apache Impala that is installed on your machine, including the version number.

Linux Connector

This section provides an overview of the Connector in the Linux platform, outlining the required system specifications and the steps for installing and configuring the connector in Linux environments.

For most Linux distributions, you can install the connector using the RPM file. If you are installing the connector on a Debian machine, you must use the Debian package.

Linux System Requirements

The Cloudera ODBC Connector for Apache Impala is expected to be compatible with all supported CDP and CDW versions.

Install the connector on client machines where the application is installed. Each client machine that you install the connector on must meet the following minimum system requirements:

- One of the following distributions:
 - Red Hat® Enterprise Linux® (RHEL) 8 or 9
 - SUSE Linux Enterprise Server (SLES) 15
 - Debian 11 or 12
 - Ubuntu 22.04 or 24.04
- 50MB of available disk space
- One of the following ODBC driver managers installed:
 - o iODBC 3.52.9 or later
 - unixODBC 2.2.14 or later
- All of the following libsasl libraries installed:
 - o cyrus-sasl-2.1.22-7 or later
 - o cyrus-sasl-gssapi-2.1.22-7 or later
 - o cyrus-sasl-plain-2.1.22-7 or later

Note: If the package manager in your Linux distribution cannot resolve the dependencies automatically when installing the connector, then download and manually install the packages.

To install the connector, you must have root access on the machine.

Installing the Connector Using the RPM File

On 64-bit editions of Linux, you can execute both 32- and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use a connector whose bitness matches the bitness of the client application:

- ClouderaImpalaODBC-32bit-[Version]-[Release].i686.rpm for the 32-bit connector
- ClouderaImpalaODBC-[Version]-[Release].x86 64.rpm for the 64-bit connector

The placeholders in the file names are defined as follows:

- [Version] is the version number of the connector.
- [Release] is the release number for this version of the connector.

You can install both the 32-bit and 64-bit versions of the connector on the same machine.

To install the Cloudera ODBC Connector for Apache Impala using the RPM File:

- 1. Log in as the root user.
- 2. Navigate to the folder containing the RPM package for the connector.
- 3. Depending on the Linux distribution that you are using, run one of the following commands from the command line, where [RPMFileName] is the file name of the RPM package:
 - If you are using Red Hat Enterprise Linux or CentOS, run the following command:

```
yum --nogpgcheck localinstall [RPMFileName]
```

• Or, if you are using SUSE Linux Enterprise Server, run the following command:

```
zypper install [RPMFileName]
```

The Cloudera ODBC Connector for Apache Impala files are installed in the /opt/cloudera/impalaodbc directory.

Note: If the package manager in your Linux distribution cannot resolve the libsasl dependencies automatically when installing the connector, then download and manually install the packages.

Next, configure the environment variables on your machine to make sure that the ODBC Driver manager can work with the connector. For more information, see Configuring the ODBC Driver Manager in Non-Windows Machines

Uninstalling the Connector from the Command Line

If you installed the Cloudera ODBC Connector for Apache Impala on RPM file, you can uninstall the connector from the command line.

To uninstall the Cloudera ODBC Connector for Apache Impala from the command line:

■ In the command line, where [packagename] is the file name of the RPM package, run the following command:

rpm -e --nodeps [packagename]

Installing the Connector on Debian

To install the connector on a Debian machine, use the Debian package instead of the RPM file or tarball package.

On 64-bit editions of Debian(Non-ARM machine), you can execute both 32- and 64-bit applications. In this case, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use the version of the connector that matches the bitness of the client application:

- clouderaimpalaodbc-32bit[Version]-[Release] i386.deb for the 32-bit connector
- clouderaimpalaodbc[Version]-[Release] amd64.deb for the 64-bit connector

[Version] is the version number of the connector, and [Release] is the release number for this version of the connector.

You can install both versions of the connector on the same machine.

To install the Cloudera ODBC Connector for Apache Impala on Debian:

- 1. Log in as the root user, and then navigate to the folder containing the Debian package for the connector.
- 2. Double-click clouderaimpalaodbc-32bit/Version]-[Release]_i386.deb or clouderaimpalaodbc [Version]-[Release]_amd64.deb.
- 3. Follow the instructions in the installer to complete the installation process.

The Cloudera ODBC Connector for Apache Impala files are installed in the /opt/cloudera/impalaodbc directory.

Note: If the package manager in your Ubuntu distribution cannot resolve the libsasl dependencies automatically when installing the connector, then download and manually install the packages required by the version of the connector that you want to install.

Next, configure the environment variables on your machine to make sure that the ODBC driver manager can work with the connector. For more information, see Configuring the ODBC Driver Manager in Non-Windows Machines.

Verifying the Connector Version Number in Linux

If you need to verify the version of the Cloudera ODBC Connector for Apache Impala that is installed on your Linux machine, you can guery the version number through the command-line interface if the connector was installed using an RPM file or Debian package. Alternatively, you can search the connector's binary file for version number information.

To verify the connector version number in Linux using the command-line interface:

Depending on your package manager, at the command prompt, run one of the following commands:

Linux Connector

- yum list | grep ClouderalmpalaODBC
- rpm -qa | grep ClouderalmpalaODBC
- dpkg -l | grep clouderaimpalaodbc

The command returns information about the Cloudera ODBC Connector for Apache Impala that is installed on your machine, including the version number.

To verify the connector version number in Linux using the binary file:

- 1. Navigate to the /lib subfolder in your connector installation directory. By default, the path to this directory is: /opt/cloudera/impalaodbc/lib.
- 2. Open the connector's .so binary file in a text editor, and search for the text \$driver_version_sb\$:. The connector's version number is listed after this text.

AIX Connector

This section provides an overview of the Connector in the AIX platform, outlining the required system specifications and the steps for installing and configuring the connector in AIX environments.

AIX System Requirements

The Cloudera ODBC Connector for Apache Impala is expected to be compatible with all supported CDP and CDW versions.

Install the connector on client machines where the application is installed. Each machine that you install the connector on must meet the following minimum system requirements:

- IBM AIX 7.1 or 7.2
- 150 MB of available disk space
- One of the following ODBC driver managers installed:
 - iODBC 3.52.9 or later
 - unixODBC 2.2.14 or later

To install the connector, you must have root access on the machine.

Installing the Connector on AIX

On 64-bit editions of AIX, you can execute both 32- and 64-bit applications. However, 64-bit applications must use 64-bit connectors, and 32-bit applications must use 32-bit connectors. Make sure that you use the version of the connector that matches the bitness of the client application:

- ClouderaImpalaODBC-32bit-[Version]-[Release].ppc.rpm for the 32-bit connector
- ClouderaImpalaODBC-[Version]-[Release].ppc.rpm for the 64-bit connector

[Version] is the version number of the connector, and [Release] is the release number for this version of the connector.

You can install both versions of the connector on the same machine.

To install the Cloudera ODBC Connector for Apache Impala on AIX:

- Log in as the root user, and then navigate to the folder containing the RPM package for the connector.
- 2. Run the following command from the command line, where [RPMFileName] is the file name of the RPM package:

```
rpm --install [RPMFileName]
```

The Cloudera ODBC Connector for Apache Impala files are installed in the /opt/cloudera/impalaodbc directory.

Next, configure the environment variables on your machine to make sure that the ODBC driver manager can work with the connector. For more information, see Configuring the ODBC Driver Manager in Non-Windows Machines.

Verifying the Connector Version Number on AIX

If you need to verify the version of the Cloudera ODBC Connector for Apache Impala that is installed on your AIX machine, you can query the version number through the command-line interface.

To verify the connector version number on AIX:

At the command prompt, run the following command:

```
rpm -qa | grep ClouderaImpalaODBC
```

The command returns information about the Cloudera ODBC Connector for Apache Impala that is installed on your machine, including the version number.

Configuring the ODBC Driver Manager in Non-Windows Machines

To make sure that the ODBC Driver manager on your machine is configured to work with the Cloudera ODBC Connector for Apache Impala, do the following:

- Set the library path environment variable to make sure that your machine uses the correct ODBC Driver manager. For more information, see Specifying ODBC Driver Managers in Non-Windows Machines.
- If the connector configuration files are not stored in the default locations expected by the ODBC driver manager, then set environment variables to make sure that the Driver manager locates and uses those files. For more information, see Specifying the Locations of the Connector Configuration Files.

After configuring the ODBC Driver manager, you can configure a connection and access your data store through the connector.

Specifying ODBC Driver Managers in Non-Windows Machines

You need to make sure that your machine uses the correct ODBC Driver manager to load the connector. To do this, set the library path environment variable.

macOS

If you are using a macOS machine, then set the DYLD_LIBRARY_PATH environment variable to include the paths to the ODBC driver manager libraries. For example, if the libraries are installed in /usr/local/lib, then run the following command to set DYLD_LIBRARY_PATH for the current user session:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/usr/local/lib
```

For information about setting an environment variable permanently, refer to the macOS shell documentation.

Linux or AIX

If you are using a Linux or AIX machine, then set the LD_LIBRARY_PATH environment variable to include the paths to the ODBC driver manager libraries. For example, if the libraries are installed in /usr/local/lib, then run the following command to set LD_LIBRARY_PATH for the current user session:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/local/lib
```

For information about setting an environment variable permanently, refer to the Linux or AIX shell documentation.

Specifying the Locations of the Connector Configuration Files

By default, ODBC Driver managers are configured to use hidden versions of the odbc.ini and odbcinst.ini configuration files (named .odbc.ini and .odbcinst.ini) located in the home directory, as well as the cloudera.impalaodbc.ini file in the lib subfolder of the connector installation directory. If you store these configuration files elsewhere, then you must set the environment variables described below so that the driver manager can locate the files.

If you are using iODBC, do the following:

- Set ODBCINI to the full path and file name of the odbc.ini file.
- Set ODBCINSTINI to the full path and file name of the odbcinst.ini file.
- Set CLOUDERAIMPALAINI to the full path and file name of the cloudera.impalaodbc.ini file.

If you are using unixODBC, do the following:

- Set ODBCINI to the full path and file name of the odbc.ini file.
- Set ODBCSYSINI to the full path of the directory that contains the odbcinst.ini file.
- Set CLOUDERAIMPALAINI to the full path and file name of the cloudera.impalaodbc.ini file.

For example, if your odbc.ini and odbcinst.ini files are located in /usr/local/odbc and your cloudera.impalaodbc.ini file is located in /etc, then set the environment variables as follows:

For iODBC:

export ODBCINI=/usr/local/odbc/odbc.ini
export ODBCINSTINI=/usr/local/odbc/odbcinst.ini
export CLOUDERAIMPALAINI=/etc/cloudera.impalaodbc.ini

For unixODBC:

export ODBCINI=/usr/local/odbc/odbc.ini
export ODBCSYSINI=/usr/local/odbc

export CLOUDERAIMPALAINI=/etc/cloudera.impalaodbc.ini

To locate the cloudera.impalaodbc.ini file, the connector uses the following search order:

- 1. If the CLOUDERAIMPALAINI environment variable is defined, then the connector searches for the file specified by the environment variable.
- 2. The connector searches the directory that contains the connector library files for a file named cloudera.impalaodbc.ini.

Configuring the ODBC Driver Manager in Non-Windows Machines

- 3. The connector searches the current working directory of the application for a file named cloudera.impalaodbc.ini.
- 4. The connector searches the home directory for a hidden file named cloudera.impalaodbc.ini (prefixed with a period).
- 5. The connector searches the /etc directory for a file named cloudera.impalaodbc.ini.

Configuring ODBC Connections in Non-Windows Machine

The following sections describe how to configure ODBC connections when using the Cloudera ODBC Connector for Apache Impala on non-Windows platforms:

- Creating a Data Source Name on a Non-Windows Machine
- Configuring a DSN-less Connection in a Non-Windows Machine
- Configuring Authentication on a Non-Windows Machine
- Configuring SSL Verification in a Non-Windows Machine
- Configuring Server-Side Properties on a Non-Windows Machine
- Configuring Logging Options
- Setting Connector-Wide Configuration Options on a Non-Windows Machine
- Testing the Connection

Creating a Data Source Name on a Non-Windows Machine

Typically, after installing the Cloudera ODBC Connector for Apache Impala, you need to create a Data Source Name (DSN). A DSN is a data structure that stores connection information so that it can be used by the connector to connect to Impala.

You can specify connection settings in a DSN (in the odbc.ini file), in a connection string, or as connector-wide settings (in the cloudera.impalaodbc.ini file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

The following instructions describe how to create a DSN by specifying connection settings in the odbc.ini file. If your machine is already configured to use an existing odbc.ini file, then update that file by adding the settings described below. Otherwise, copy the odbc.ini file from the Setup subfolder in the connector installation directory to the home directory, and then update the file as described below.

For information about specifying settings in a connection string, see Configuring a DSN-less Connection in a Non-Windows Machine and Using a Connection String. For information about connector-wide settings, see Setting Connector-Wide Configuration Options on a Non-Windows Machine.

To create a Data Source Name on a non-Windows machine:

1. In a text editor, open the odbc.ini configuration file.

Note: If you are using a hidden copy of the odbc.ini file, you can remove the period (.) from the start of the file name to make the file visible while you are editing it.

2. In the [ODBC Data Sources] section, add a new entry by typing a name for the DSN, an equal sign (=), and then the name of the connector.

For example, on a macOS machine:

[ODBC Data Sources]

Sample DSN=Cloudera ODBC Driver for Impala

As another example, for a 32-bit connector on a Linux/AIX/Debian machine:

[ODBC Data Sources]

Sample DSN=Cloudera ODBC Driver for Impala 32-bit

- 3. Create a section that has the same name as your DSN, and then specify configuration options as key-value pairs in the section:
 - a. Set the Driver property to the full path of the connector library file that matches the bitness of the application.

For example, on a macOS machine:

Driver=/opt/cloudera/impalaodbc/lib/universal/libclouderaimpalaodbc.dylib

As another example, for a 32-bit connector on a Linux/AIX/Debian machine:

Driver=/opt/cloudera/impalaodbc/lib/32/libclouderaimpalaodbc32.so

b. Set the <code>Host</code> property to the IP address or host name of the server.

For example:

Host=192.168.222.160

c. Set the Port property to the number of the TCP port that the server uses to listen for client connections.

For example:

Port=21050

- d. If authentication is required to access the server, then specify the authentication mechanism and your credentials. For more information, see Configuring Authentication on a Non-Windows Machine.
- e. If you want to connect to the server through SSL, then enable SSL and specify the certificate information. For more information, see Configuring SSL Verification in a Non-Windows Machine.
- f. If you want to configure server-side properties, then set them as key-value pairs using a special syntax. For more information, see Configuring Server-Side Properties on a Non-Windows Machine.
- g. Optionally, set additional key-value pairs as needed to specify other optional connection settings. For detailed information about all the configuration options supported by the Cloudera ODBC Connector for Apache Impala, see Connector Configuration Options.
- 4. Save the odbc.ini configuration file.

Note:

If you are storing this file in its default location in the home directory, then prefix the file name with a period (.) so that the file becomes hidden. If you are storing this file in another location, then save it as a non-hidden file (without the prefix), and make sure that the ODBCINI environment variable specifies the location. For more information, see Specifying the Locations of the Connector Configuration Files.

For example, the following is an odbc.ini configuration file for macOS containing a DSN that connects to an Impala server that does not require authentication:

[ODBC Data Sources]

Sample DSN=Cloudera ODBC Driver for Impala

[Sample DSN]

Driver=/opt/cloudera/impalaodbc/lib/universal/libclouderaimpalaodbc.dylib

Host=192.168.222.160

Port=21050

As another example, the following is an odbc.ini configuration file for a 32-bit connector on a Linux/AIX/Debian machine, containing a DSN that connects to an Impala server that does not require authentication:

[ODBC Data Sources]

Sample DSN=Cloudera ODBC Driver for Impala 32-bit

[Sample DSN]

Driver=/opt/cloudera/impalaodbc/lib/32/libclouderaimpalaodbc32.so

Host=192.168.222.160

Port=21050

You can now use the DSN in an application to connect to the data store.

Configuring a DSN-less Connection in a Non-Windows Machine

To connect to your data store through a DSN-less connection, you need to define the connector in the odbcinst.ini file and then provide a DSN-less connection string in your application.

If your machine is already configured to use an existing odbcinst.ini file, then update that file by adding the settings described below. Otherwise, copy the odbcinst.ini file from the Setup subfolder in the connector installation directory to the home directory, and then update the file as described below.

To define a connector on a non-Windows machine:

1. In a text editor, open the odbcinst.ini configuration file.

Note: If you are using a hidden copy of the odbcinst.ini file, you can remove the period (.) from the start of the file name to make the file visible while you are editing it.

2. In the [ODBC Drivers] section, add a new entry by typing a name for the connector, an equal sign (=), and then Installed.For example:

Cloudera ODBC Driver for Impala=Installed

- 3. Create a section that has the same name as the connector (as specified in the previous step), and then specify the following configuration options as key-value pairs in the section:
 - a. Set the Driver property to the full path of the connector library file that matches the bitness of the application.

For example, on a macOS machine:

Driver=/opt/cloudera/impalaodbc/lib/universal/libclouderaimpalaodbc .dylib

As another example, for a 32-bit connector on a Linux/AIX/Debian machine:

Driver=/opt/cloudera/impalaodbc/lib/32/libclouderaimpalaodbc32.so

b. Optionally, set the Description property to a description of the connector. For example:

Description=Cloudera ODBC Driver for Impala

4. Save the odbcinst.ini configuration file.

Note: If you are storing this file in its default location in the home directory, then prefix the file name with a period (.) so that the file becomes hidden. If you are storing this file in another location, then save it as a non-hidden file (without the prefix), and make sure that the ODBCINSTINI or ODBCSYSINI environment variable specifies the location. For more information, see Specifying the Locations of the Connector Configuration Files.

For example, the following is an odbcinst.ini configuration file for macOS:

[ODBC Drivers]

Cloudera ODBC Driver for Impala=Installed

Configuring ODBC Connections in Non-Windows Machine

```
[Cloudera ODBC Driver for Impala]

Description=Cloudera ODBC Driver for Impala

Driver=/opt/cloudera/impalaodbc/lib/universal/libclouderaimpalaodbc.dylib
```

As another example, the following is an odbcinst.ini configuration file for both the 32- and 64-bit connectors in Linux/AIX/Debian:

```
[ODBC Drivers]

Cloudera ODBC Driver for Impala 32-bit=Installed

Cloudera ODBC Driver for Impala 64-bit=Installed

[Cloudera ODBC Driver for Impala 32-bit]

Description=Cloudera ODBC Driver for Impala (32-bit)

Driver=/opt/cloudera/impalaodbc/lib/32/libclouderaimpalaodbc32.so

[Cloudera ODBC Driver for Impala 64-bit]

Description=Cloudera ODBC Driver for Impala (64-bit)

Driver=/opt/cloudera/impalaodbc/lib/64/libclouderaimpalaodbc64.so
```

You can now connect to your data store by providing your application with a connection string where the <code>Driver</code> property is set to the connector name specified in the <code>odbcinst.ini</code> file, and all the other necessary connection properties are also set. For more information, see "DSN-less Connection String Examples" in Using a Connection String.

For detailed information about all the connection properties that the connector supports, see Connector Configuration Options.

Configuring Authentication on a Non-Windows Machine

Some Impala servers are configured to require authentication for access. To connect to an Impala server, you must configure the Cloudera ODBC Connector for Apache Impala to use the authentication mechanism that matches the access requirements of the server and provides the necessary credentials.

For information about how to determine the type of authentication your Impala server requires, see Authentication Options.

You can set the connection properties for authentication in a connection string, in a DSN (in the odbc.ini file), or as a connector-wide setting (in the cloudera.impalaodbc.ini file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

The following authentication methods are available:

- Using No Authentication
- Using Kerberos
- Using Advanced Kerberos
- Using SAML 2.0
- Using SASL User Name
- Using JSON Web Token (JWT)
- Using User Name And Password
- Using OAuth 2.0

If cookie-based authentication is enabled in your Impala database, you can specify a list of authentication cookies in the HTTPAuthCookies connection property. In this case, the connector authenticates the connection once based on the provided authentication credentials. It then uses the cookie generated by the server for each subsequent request in the same connection. For more information, see HTTPAuthCookies.

Using No Authentication

For this authentication mechanism, you do not need to configure any additional settings.

Note: The default configuration of Impala requires the Cloudera ODBC Connector for Apache Impala to be configured to use the No Authentication mechanism.

To configure a connection without authentication:

- 1. Set the AuthMech connection attribute to No Authentication.
- 2. If the Impala server is configured to use SSL, then configure SSL for the connection. For more information, see Configuring SSL Verification in a Non-Windows Machine.

Using Kerberos

Kerberos must be installed and configured before you can use this authentication mechanism. For more information, refer to the MIT Kerberos Documentation: http://web.mit.edu/kerberos/krb5-latest/doc/.

To configure Kerberos authentication:

- 1. Set the AuthMech connection attribute to Kerberos.
- 2. Choose one:
 - To use the default realm defined in your Kerberos setup, do not set the KrbRealm attribute.
 - Or, if your Kerberos setup does not define a default realm or if the realm of your Impala server is not the default, then set the appropriate realm using the KrbRealm attribute.
- Optionally, if you are using MIT Kerberos and a Kerberos realm is specified using the KrbRealm connection attribute, then choose one:
 - To have the Kerberos layer canonicalize the server's service principal name, leave the ServicePrincipalCanonicalization attribute set to 1.
 - Or, to prevent the Kerberos layer from canonicalizing the server's service principal name, set the ServicePrincipalCanonicalization attribute to 0.
- 4. Set the KrbFQDN attribute to the fully qualified domain name of the Impala server host.
 - Note: To use the Impala server host name as the fully qualified domain name for Kerberos authentication, set KrbFQDN to HOST.
- 5. Set the KrbServiceName attribute to the service name of the Impala server.
- 6. Optionally, set the TSaslTransportBufSize attribute to the number of bytes to reserve in memory for buffering unencrypted data from the network.
 - Note: In most circumstances, the default value of 1000 bytes is optimal.

Using Advanced Kerberos

This authentication mechanism allows concurrent connections within the same process to use different Kerberos user principals.

When you use Advanced Kerberos authentication, you do not need to run the kinit command to obtain a Kerberos ticket. Instead, you use a JSON file to map your Impala user name to a Kerberos user principal name and a keytab that contains the corresponding keys. The connector obtains Kerberos tickets based on the specified mapping. As a fallback, you can specify a keytab that the connector uses by default if the mapping file is not available or if no matching keytab can be found in the mapping file.

Note:

- For information about the schema of the mapping file and how the connector handles invalid mappings, see UPN Keytab Mapping File.
- For information about how the connector searches for a keytab file if the keytab mapping and default keytab file are invalid, see Default Keytab File.

To configure Advanced Kerberos authentication:

- 1. Set the AuthMech connection attribute to Kerberos.
- 2. Choose one:
- To use the default realm defined in your Kerberos setup, do not set the KrbRealm attribute.
- Or, if your Kerberos setup does not define a default realm or if the realm of your Impala server is not the default, then set the appropriate realm using the KrbRealm attribute.
- 3. Optionally, if you are using MIT Kerberos and a Kerberos realm is specified using the KrbRealm connection attribute, then choose one:
- To have the Kerberos layer canonicalize the server's service principal name, leave the ServicePrincipalCanonicalization attribute set to 1.
- Or, to prevent the Kerberos layer from canonicalizing the server's service principal name, set the ServicePrincipalCanonicalization attribute to 0.
- 4. Set the KrbFQDN attribute to the fully qualified domain name of the Impala server host.

Note:

To use the Impala server host name as the fully qualified domain name for Kerberos authentication, set KrbFQDN to HOST.

- 5. Set the KrbServiceName attribute to the service name of the Impala server.
- 6. Set the UseKeytab attribute to 1.
- 7. Set the UID attribute to an appropriate user name for accessing the Impala server.
- 8. Set the UPNKeytabMappingFile attribute to the full path to a JSON file that maps your Impala user name to a Kerberos user principal name and a keytab file.
- 9. Set the DefaultKeytabFile attribute to the full path to a keytab file that the connector can use if the mapping file is not available or if no matching keytab can be found in the mapping file.
- 10. If the Impala server is configured to use SSL, then configure SSL for the connection. For more information, see Configuring SSL Verification in a Non-Windows Machine.
- 11. Optionally, set the TSaslTransportBufSize attribute to the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note:

In most circumstances, the default value of 1000 bytes is optimal.

Using SAML 2.0

This authentication mechanism enables you to authenticate via Single Sign-On using SAML 2.0 against supported servers.

Important: In order to use SAML 2.0 for authentication, the TransportMode attribute must be set to HTTP and the SSL attribute must be set to 1.

To configure SAML 2.0 authentication:

- 1. Set the AuthMech connection attribute to SAML 2.0.
- 2. Set the TransportMode attribute to HTTP.
- 3. Set the HttpPath attribute to the partial URL corresponding to the Impala server.
- 4. Set the SSL attribute to 1.
- 5. Optionally, set the SSOIgnoreDriverNoPrompt attribute to true. When the application is making a SQLDriverConnect call with a SQL_DRIVER_NOPROMPT flag, this property displays the web browser used to complete the browser based authentication flow.
- 6. Optionally, set the TSaslTransportBufSize attribute to the number of bytes to reserve in memory for buffering unencrypted data from the network.

Note: In most circumstances, the default value of 1000 bytes is optimal.

Using SASL User Name

This authentication mechanism requires a user name but does not require a password. The user name labels the session, facilitating database tracking.

To configure SASL User Name authentication:

- 1. Set the AuthMech connection attribute to SASL User Name.
- 2. Set the UID attribute to an appropriate user name for accessing the Impala server.
- 3. Optionally, set the TSaslTransportBufSize attribute to the number of bytes to reserve in memory for buffering unencrypted data from the network.

Using JSON Web Token (JWT)

This authentication mechanism enables you to authenticate via JSON Web Token against supported servers.

Important:

In order to use JWT for authentication, TransportMode must be set to HTTP and JWTString must be specified in the connection string.

To configure JWT authentication:

- 1. Set the AuthMech connection attribute to JWT or 8.
- 2. Set the TransportMode attribute to HTTP.
- 3. Set the JWTString attribute in the connection string.

You can now use the connector to authenticate through JWT and connect to your Impala server.

Using User Name And Password

This authentication mechanism requires a user name and a password.

Note: This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled.

To configure User Name And Password authentication:

- 1. Set the AuthMech connection attribute to User Name and Password.
- 2. Set the UID attribute to an appropriate user name for accessing the Impala server.
- 3. Set the PWD attribute to the password corresponding to the user name you provided above.
- 4. Optionally, set the TSaslTransportBufSize attribute to the number of bytes to reserve in memory for buffering unencrypted data from the network.
 - Note: In most circumstances, the default value of 1000 bytes is optimal.
- 5. Optionally, to use SASL to handle authentication, set the UseSASL attribute to 1.

Note: If the Transport Mode property is specified, it takes precedence over this property.

Using OAuth 2.0

Three types of authentication work flow are available when using OAuth 2.0, token pass-through, client credentials, or browser based authentication.

When you use OAuth 2.0 authentication, HTTP is the only transport mode protocol available.

Token Pass-through

This authentication mechanism requires a valid OAuth 2.0 access token. Be aware that access tokens typically expire after a certain amount of time, after which you must either refresh the token or obtain a new one from the server. To obtain a new access token, see Obtaining a New Access Token.

Configuring ODBC Connections in Non-Windows Machine

To configure OAuth 2.0 token pass-though authentication:

- 1. Set the AuthMech property to OAuth 2.0.
- 2. Set the Auth Flow property to 0.
- 3. Set the Auth AccessToken property to your access token.

Obtaining a New Access Token

Once an access token expires, you can obtain a new access token for the connector.

Note: When an access token expires, the connector returns a "SQLState 08006" error.

To obtain a new access token:

- 1. In the connection string, set the Auth AccessToken property with a new access token.
- 2. Call the SQLSetConnectAttr function with SQL_ATTR_CREDENTIALS (122) as the attribute and the new connection string as the value. The connector will update the current connection string with the new access token.

Note: Calling the SQLGetConnectAttr function with SQL_ATTR_CREDENTIALS (122) returns the entire connection string used during connection.

- 3. Call the SQLSetConnectAttr function with SQL_ATTR_REFRESH_CONNECTION (123) as the attribute and SQL_REFRESH_NOW (-1) as the value. This signals the connector to update the access token value.
- 4. Retry the previous ODBC API call. After obtaining the new access token, the open connection, statements, and cursors associated with it remain valid for use.

Client Credentials

This authentication mechanism requires SSL to be enabled.

To configure OAuth 2.0 client credentials authentication:

- 1. Set the AuthMech property to OAuth 2.0.
- 2. Set the Auth Flow property to 1.
- 3. Set the Auth Client ID to your client ID.
- 4. Set the Auth Client Secret to your client secret.
- 5. Set the Auth_Audience to your OAuth audience.
- 6. Set the OAuth2TokenEndPoint to your token endpoint.
- 7. Optionally, set the Auth Scope to your OAuth scope.

Browser Based

This authentication mechanism requires SSL to be enabled.

To configure OAuth 2.0 browser based authentication:

- 1. Set the AuthMech property to 11.
- 2. Set the Auth Flow property to 2.
- 3. Set the Auth Client ID to your client ID.
- 4. Set the Auth Client Secret to your client secret.
- 5. Set the Auth Audience to your OAuth audience.
- 6. Set the OAuth2TokenEndPoint to your token endpoint.
- 7. Set the <code>OAuth2AuthorizationEndPoint</code> to your authorization endpoint.
- 8. Set the TokenCachePassPhrase property to a password of your choice. This is the key used for refresh token encryption.
- 9. Optionally, set the Auth_Scope to your OAuth scope.

Configuring SSL Verification in a Non-Windows Machine

If you are connecting to an Impala server that has Secure Sockets Layer (SSL) enabled, you can configure the connector to connect to an SSL-enabled socket. When using SSL to connect to a server, the connector can be configured to verify the identity of the server.

You can set the connection properties described below in a connection string, in a DSN (in the odbc.ini file), or as a connector-wide setting (in the cloudera.impalaodbc.ini file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To configure SSL verification on a non-Windows machine:

- 1. To enable SSL connections, set the SSL attribute to 1.
- 2. To allow authentication using self-signed certificates that have not been added to the list of trusted certificates, set the AllowSelfSignedServerCert attribute to 1.
- 3. To allow the common name of a CA-issued SSL certificate to not match the host name of the Impala server, set the <code>AllowHostNameCNMismatch</code> attribute to 1.
- 4. Choose one:
 - To configure the connector to load SSL certificates from a specific .pem file when verifying the server, set the TrustedCerts attribute to the full path of the .pem file.
 - Or, to use the trusted CA certificates . pem file that is installed with the connector, do not specify a value for the TrustedCerts attribute.
- 5. To allow authentication, when the certificate's revocation status is undetermined, set the CheckCertRevocation attribute to 1.
- 6. To specify the minimum version of TLS to use, set the Min_{TLS} property to the minimum version of TLS. Supported options include 1.0 for TLS 1.0, 1.1 for TLS 1.1, and 1.2 for TLS 1.2

Configuring Server-Side Properties on a Non-Windows Machine

When connecting to a server that is running Impala 2.0 or later, you can use the connector to apply configuration properties to the Impala server.

You can set the connection properties described below in a connection string, in a DSN (in the odbc.ini file), or as a connector-wide setting (in the cloudera.impalaodbc.ini file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

Important:

This feature is not supported for earlier versions of Impala, where the SET statement can only be executed from within the Impala shell.

To configure server-side properties on a non-Windows machine:

1. To set a server-side property, use the syntax SSP [SSPKey]=[SSPValue], where [SSPKey] is the name of the server-side property and [SSPValue] is the value to specify for that property. For example, to set the MEM_LIMIT query option to 1 GB and the REQUEST_POOL query option to myPool, type the following in the odbc.ini file:

```
SSP MEM LIMIT=1000000000
SSP REQUEST POOL=myPool
```

Or, to set those properties in a connection string, type the following:

```
SSP MEM LIMIT={1000000000}; SSP REQUEST POOL={myPool}
```

Note: When setting a server-side property in a connection string, it is recommended that you enclose the value in braces ({ }) to make sure that special characters can be properly escaped.

2. To disable the connector's default behavior of converting server-side property key names to all lower-case characters, set the LCaseSspKeyName property to 0.

Configuring Logging Options

To help troubleshoot issues, you can enable logging in the connector.

Important: Only enable logging long enough to capture an issue. Logging decreases performance and can consume a large quantity of disk space.

You can set the connection properties described below in a connection string, in a DSN (in the odbc.ini file), or as a connector-wide setting (in the cloudera.impalaodbc.ini file). Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To enable logging:

1. To specify the level of information to include in log files, set the LogLevel property to one of the following numbers:

LogLevel Value	Description
0	Disables all logging.
1	Logs severe error events that lead the connector to abort.
2	Logs error events that might allow the connector to continue running.
3	Logs events that might result in an error if action is not taken.
4	Logs general information that describes the progress of the connector.
5	Logs detailed information that is useful for debugging the connector.
6	Logs all connector activity.

- 2. Set the LogPath key to the full path to the folder where you want to save log files.
- 3. Set the LogFileCount key to the maximum number of log files to keep.
 - Note: After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.
- 4. Set the LogFileSize key to the maximum size of each log file in bytes.
 - Note: After the maximum file size is reached, the connector creates a new file and continues logging.
- 5. Optionally, to prefix the log file name with the user name and process ID associated with the connection, set the UseLogPrefix property to 1.
- 6. Save the cloudera.impalaodbc.ini configuration file.
- 7. Restart your ODBC application to make sure that the new settings take effect.

The Cloudera ODBC Connector for Apache Impala produces the following log files at the location you specify using the LogPath key:

- Aclouderaodbcdriverforimpala.log file that logs connector activity that is not specific to a connection.
- A clouderaodbcdriverforimpala_connection_[Number].log file for each connection made to the database, where [Number] is a number that identifies each log file. This file logs connector activity that is specific to the connection.

If you set the <code>UseLogPrefix</code> property to 1, then each file name is prefixed with <code>[UserName]_[ProcessID]_</code>, where <code>[UserName]</code> is the user name associated with the connection and <code>[ProcessID]</code> is the process <code>ID</code> of the application through which the connection is made. For more information, see <code>UseLogPrefix</code>.

To disable logging:

- 1. Set the LogLevel key to 0.
- 2. Save the cloudera.impalaodbc.ini configuration file.
- 3. Restart your ODBC application to make sure that the new settings take effect.

Setting Connector-Wide Configuration Options on a Non-Windows Machine

When you specify connection settings in a DSN or connection string, those settings apply only when you connect to Impala using that particular DSN or string. As an alternative, you can specify settings that apply to every connection that uses the Cloudera ODBC Connector for Apache Impala by configuring them in the cloudera.impalaodbc.ini file.

Note: Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

To set connector-wide configuration options on a non-Windows machine:

- 1. In a text editor, open the cloudera.impalaodbc.ini configuration file.
- 2. In the [Driver] section, specify configuration options as key-value pairs. Start a new line for each key-value pair.

For example, to enable SASL User Name authentication using "cloudera" as the user name, type the following:

```
AuthMech=SASL User Name
UID=cloudera
```

For detailed information about all the configuration options supported by the connector, see Connector Configuration Options.

3. Save the cloudera.impalaodbc.ini configuration file.

Testing the Connection

To test the connection, you can use an ODBC-enabled client application. For a basic connection test, you can also use the test utilities that are packaged with your driver manager installation. For example, the iODBC driver manager includes simple utilities called iodbctest and iodbctestw. Similarly, the unixODBC driver manager includes simple utilities called isql and iusql.

Using the iODBC Driver Manager

You can use the iodbctest and iodbctestw utilities to establish a test connection with your connector. Use iodbctest to test how your connector works with an ANSI application, or use iodbctestw to test how your connector works with a Unicode application.

Note: There are 32-bit and 64-bit installations of the iODBC driver manager available. If you have only one or the other installed, then the appropriate version of iodbctest (or iodbctestw) is available. However, if you have both 32- and 64-bit versions installed, then you need to make sure that you are running the version from the correct installation directory.

For more information about using the iODBC driver manager, see http://www.iodbc.org.

To test your connection using the iODBC driver manager:

- Run iodbctest or iodbctestw.
- 2. Optionally, if you do not remember the DSN, then type a question mark (?) to see a list of available DSNs.
- 3. Type the connection string for connecting to your data store, and then press ENTER. For more information, see Using a Connection String.

If the connection is successful, then the SQL> prompt appears.

Using the unixODBC Driver Manager

You can use the isql and iusql utilities to establish a test connection with your connector and your DSN. isql and iusql can only be used to test connections that use a DSN. Use isql to test how your connector works with an ANSI application, or use iusql to test how your connector works with a Unicode application.

Note: There are 32-bit and 64-bit installations of the unixODBC driver manager available. If you have only one or the other installed, then the appropriate version of isql (or iusql) is available. However, if you have both 32- and 64-bit versions installed, then you need to make sure that you are running the version from the correct installation directory.

For more information about using the unixODBC driver manager, see http://www.unixodbc.org.

To test your connection using the unixODBC driver manager:

- Run isql or iusql by using the corresponding syntax:
 - isql [DataSourceName]
 - iusql [DataSourceName]

[DataSourceName] is the DSN that you are using for the connection.

If the connection is successful, then the SQL> prompt appears.

Note: For information about the available options, run isql or iusql without providing a DSN.

Authentication Options

Impala supports multiple authentication mechanisms. You must determine the authentication type that your server is using. The authentication methods available in the Cloudera ODBC Connector for Apache Impala are as follows:

- No Authentication
- Kerberos
- SAML 2.0
- SASL User Name
- JWT
- User Name And Password

Note:

- The default configuration of Impala requires the Cloudera ODBC Connector for Apache Impala to be configured to use the No Authentication mechanism.
- In addition to regular Kerberos authentication, the connector also supports an advanced configuration of Kerberos authentication that allows concurrent connections within the same process to use different Kerberos user principals.

In addition to authentication, you can configure the connector to connect over SSL or use SASL to handle authentication.

The Impala server uses SASL (Simple Authentication and Security Layer) to support some of the authentication methods. Kerberos is supported with the SASL GSSAPI mechanism. SASL User Name and User Name And Password (with SASL enabled) are supported with the SASL PLAIN mechanism.

SASL mechanisms	Non-SASL mechanisms
 Kerberos SASL User Name User Name And Password (with SASL enabled) 	 No Authentication SAML 2.0 JWT User Name And Password (without SASL enabled)

Note:

Thrift (the layer for handling remote process communication between the Cloudera ODBC Connector for Apache Impala and the Impala server) has a limitation where it cannot detect a mix of non-SASL and SASL mechanisms being used between the connector and the server. If this happens, the connector will appear to hang during connection establishment.

Using a Connection String

For some applications, you might need to use a connection string to connect to your data source. For detailed information about how to use a connection string in an ODBC application, refer to the documentation for the application that you are using.

The connection strings in the following sections are examples showing the minimum set of connection attributes that you must specify to successfully connect to the data source. Depending on the configuration of the data source and the type of connection you are working with, you might need to specify additional connection attributes. For detailed information about all the attributes that you can use in the connection string, see Connector Configuration Options.

DSN Connection String Example

The following is an example of a connection string for a connection that uses a DSN:

DSN=[DataSourceName]

[DataSourceName] is the DSN that you are using for the connection.

You can set additional configuration options by appending key-value pairs to the connection string. Configuration options that are passed in using a connection string take precedence over configuration options that are set in the DSN.

DSN-less Connection String Examples

Some applications provide support for connecting to a data source using a connector without a DSN. To connect to a data source without using a DSN, use a connection string instead.

The placeholders in the examples are defined as follows, in alphabetical order:

- [AccessToken] is your access token for authenticating the connection through the OAuth 2.0 protocol.
- [DomainName] is the fully qualified domain name of the Impala server host.
- [MappingFile] is the full path to a JSON file that maps your Impala user name to a Kerberos user principal name and a keytab file.
- [PortNumber] is the number of the TCP port that the Impala server uses to listen for client connections.
- [Realm] is the Kerberos realm of the Impala server host.
- [Server] is the IP address or host name of the Impala server to which you are connecting.
- [ServiceName] is the Kerberos service principal name of the Impala server.
- [URL] is the partial URL corresponding to the the Impala server.
- [YourPassword] is the password corresponding to your user name.
- [YourUserName] is the user name that you use to access the Impala server.

Connecting to an Impala Server Without Authentication

The following is the format of a DSN-less connection string that connects to an Impala server that does not require authentication:

Driver=Cloudera ODBC Driver for Impala; Host=[Server]; Port=[PortNumber];

For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160; Port=21050;

If you are connecting to the server through SSL, then set the SSL property to 1. For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160; Port=21050;SSL=1;

Connecting to an Impala Server that Requires Kerberos Authentication

The following is the format of a DSN-less connection string that connects to an Impala server requiring Kerberos authentication:

Driver=Cloudera ODBC Driver for Impala; Host=[Server]; Port=[PortNumber];AuthMech=Kerberos;KrbRealm=[Realm]; KrbFQDN=[DomainName];KrbServiceName=[ServiceName];

For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160; Port=21050; AuthMech=Kerberos; KrbRealm=CLOUDERA; KrbFQDN=localhost.localdomain;KrbServiceName=impala;

If you are connecting to the server through SSL, then set the SSL property to 1. For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160; Port=21050; AuthMech=Kerberos; KrbRealm=CLOUDERA; KrbFQDN=localhost.localdomain;KrbServiceName=impala;SSL=1;

Connecting to an Impala Server using Advanced Kerberos Authentication

The following is the format of a DSN-less connection string that connects to an Impala server using Advanced Kerberos authentication:

Driver=Cloudera ODBC Driver for Impala: Host=[Server]; Port=[PortNumber];AuthMech=Kerberos;KrbRealm=[Realm]; KrbFQDN=[DomainName];KrbServiceName=[ServiceName]; UseKeytab=1;UID=[YourUserName]; UPNKeytabMappingFile=[MappingFile];

For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160; Port=21050; AuthMech=Kerberos; KrbRealm=CLOUDERA; KrbFQDN=localhost.localdomain;KrbServiceName=impala; UseKeytab=1;UID=cloudera;

UPNKeytabMappingFile=C:\Temp\cloudera.keytab;

If you are connecting to the server through SSL, then set the SSL property to 1. For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160;

Port=21050; AuthMech=Kerberos; KrbRealm=CLOUDERA;

KrbFQDN=localhost.localdomain;KrbServiceName=impala;

UseKeytab=1;UID=cloudera;

UPNKeytabMappingFile=C:\Temp\cloudera.keytab;SSL=1;

Connecting to an Impala Server using SAML 2.0

The following is the format of a DSN-less connection string that connects to an Impala server using SAML 2.0 authentication:

Driver=Cloudera ODBC Driver for Impala; Host=[Server];

Port=[PortNumber];AuthMech=SAML 2.0;TransportMode=http;HttpPath=[URL];SSL=1

For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160;

Port=21050;AuthMech=SAML_2.0;TransportMode=http;HttpPath=cliservice;SSL=1

Connecting to a Impala Server using a JSON Web Token (JWT)

The following is the format of a DSN-less connection string for connecting to a Impala server using a JWT:

Driver=Cloudera ODBC Driver for Impala; Host=[Server];

Port=[PortNumber];AuthMech=JWT;JWTString=[token];TransportMode=http; HttpPath=[URL]; SSL=1;

For example:

Driver=Cloudera ODBC Driver for Impala;Host=192.168.222.160;

Port= 21050; AuthMech= JWT; JWTString= s0m3t0ken5tr1ngh3re; TransportMode= http; TransportMode= http

HttpPath=cliservice; SSL=1;

Connecting to an Impala Server that Requires User Name Authentication

The following is the format of a DSN-less connection string that connects to a Impala server requiring User Name authentication. By default, the connector uses anonymous as the user name.

Driver=Cloudera ODBC Driver for Impala; Host=[Server];

Port=[PortNumber];AuthMech=SASL User Name;

For example:

Driver=Cloudera ODBC Driver for Impala; Host=192.168.222.160;

Port=21050; AuthMech=SASL User Name;

If you are connecting to the server through SSL, then set the SSL property to 1. For example:

Driver=Cloudera ODBC Driver for Impala;Host=192.168.222.160; Port=21050;AuthMech=SASL User Name;SSL=1;

Connecting to an Impala Server with LDAP Authentication or other User Name and Password Authentication Enabled

The following is the format of a DSN-less connection string that connects to an Impala server with LDAP authentication, or another form of username/password authentication, enabled:

Driver=Cloudera ODBC Driver for Impala;Host=[Server];
Port=[PortNumber];AuthMech=User Name and Password;UID=[UserName];
PWD=[Password];

For example:

Driver=Cloudera ODBC Driver for Impala;Host=192.168.222.160; Port=21050;AuthMech=User Name and Password;UID=cloudera;PWD=cloudera;

If you are connecting to the LDAP-enabled server through SSL, then set the SSL property to 1. For example:

Driver=Cloudera ODBC Driver for Impala;Host=192.168.222.160; Port=21050;AuthMech=User Name and Password;UID=cloudera;PWD=cloudera;SSL=1;

Connecting to a Impala Server that Requires OAuth 2.0 Authentication

The following is the format of a DSN-less connection string that connects to an Impala server requiring OAuth 2.0 authentication:

Token pass-through

Driver=Cloudera ODBC Driver for Impala;Host=[Server]; Port=[PortNumber];AuthMech=OAuth 2.0;Auth_Flow=0;Auth_AccessToken= [AccessToken];TransportMode=http;

For example, using token pass-through authentication:

Driver=Cloudera ODBC Driver for Impala;Host=192.168.222.160; Port=10000;AuthMech=OAuth 2.0;Auth_Flow=0;Auth_ AccessToken=P9QcyQ7prK2LwUMZMpFQ4R+6jd;TransportMode=http;

Client Credentials

Driver=Simba Impala ODBC Driver;Host=[Server];Port=[PortNumber];AuthMech=OAuth 2.0;Auth_Flow=1;Auth_Audience=[audience];Auth_Client_ID=[client_id];Auth_Client_Secret=[client_secret];OAuth2TokenEndPoint=[token_endpoint];TransportMode=http;

For example, using client credentials authentication:

Driver=Simba Impala ODBC Driver;Host=192.168.222.160;Port=10000;AuthMech=OAuth 2.0;Auth_Flow=1;Auth_Audience=https://dev-xxx.us.auth0.com/api/v2/;Auth_Client_ID=KZJdh;Auth_Client_Secret=Kw41H;OAuth2TokenEndPoint=https://dev-xxx.us.auth0.com/oauth/token;TransportMode=http;

Using a Connection String

Browser based

Driver=Simba Impala ODBC Driver;Host=[Server];Port=[PortNumber];AuthMech=OAuth 2.0;Auth_Flow=2;Auth_Audience=[audience];Auth_Client_ID=[client_id];Auth_Client_Secret=[client_secret];OAuth2TokenEndPoint=[token_endpoint];OAuth2AuthorizationEndPoint={authorization_endpoint};TransportMode=http;

For example, using browser based authentication:

Driver=Simba Impala ODBC Driver;Host=192.168.222.160;Port=10000;AuthMech=OAuth 2.0;Auth_Flow=2;Auth_Audience=https://dev-xxx.us.auth0.com/api/v2/;Auth_Client_ID=KZJdh;Auth_Client_Secret=Kw41H;OAuth2TokenEndPoint=https://dev-xxx.us.auth0.com/oauth/token;OAuth2AuthorizationEndPoint=https://dev-xxx.us.auth0.com/authorize;TransportMode=http;

Features

For more information on the features of the Cloudera ODBC Connector for Apache Impala, see the following:

- Data Types
- Catalog and Schema Support
- SQL Translation
- Server-Side Properties
- Active Directory
- Write-back
- Security and Authentication

Data Types

The Cloudera ODBC Connector for Apache Impala supports many common data formats, converting between Impala data types and SQL data types.

The table below lists the supported data type mappings.

Impala Type	SQL Type
ARRAY	SQL_VARCHAR
BIGINT	SQL_BIGINT
BOOLEAN	SQL_BOOLEAN
CHAR i Note: Only available in CDH 5.2 or later.	Note: SQL_WCHAR is returned instead if the Use SQL Unicode Types configuration option (the UseUnicodeSqlCharacterTypes key) is enabled.
Note: DATE data types are only supported in Impala 3.3 or later.	SQL_DATE
DECIMAL	SQL_DECIMAL

Impala Type	SQL Type
Note: Only available in CDH 5.2 or later.	
DOUBLE	
Note: REAL is an alias for DOUBLE.	SQL_DOUBLE
FLOAT	SQL_REAL
INT	SQL_INTEGER
MAP	SQL_VARCHAR
SMALLINT	SQL_SMALLINT
STRUCT	SQL_VARCHAR
TIMESTAMP	SQL_TIMESTAMP
TINYINT	SQL_TINYINT
	SQL_VARCHAR
VARCHAR i Note: Only available in CDH 5.2 or later.	Note: SQL_WVARCHAR is returned instead if the Use SQL Unicode Types configuration option (the UseUnicodeSqlCharacterTypes key) is enabled.

Catalog and Schema Support

The Cloudera ODBC Connector for Apache Impala supports both catalogs and schemas to make it easy for the connector to work with various ODBC applications. Since Impala only organizes tables into schemas/databases, the connector provides a synthetic catalog named IMPALA under which all of the schemas/databases are organized. The connector also maps the ODBC schema to the Impala schema/database.

SQL Translation

The Cloudera ODBC Connector for Apache Impala can parse queries locally before sending them to the Impala server. This feature allows the connector to calculate query metadata without executing the query, support query parameters, and support extra SQL features such as ODBC escape sequences and additional scalar functions that are not available in the Impala-shell tool.

Note:

The connector does not support translation for queries that reference a field contained in a nested column (an ARRAY, MAP, or STRUCT column). To retrieve data from a nested column, make sure that the query is written in valid Impala SQL syntax.

Server-Side Properties

The Cloudera ODBC Connector for Apache Impala allows you to set server-side properties via a DSN. Server-side properties specified in a DSN affect only the connection that is established using the DSN.

For more information about setting server-side properties when using the Windows connector, see Configuring Server-Side Properties in Windows. For information about setting server-side properties when using the connector on a non-Windows platform, see Configuring Server-Side Properties on a Non-Windows Machine.

Active Directory

The Cloudera ODBC Connector for Apache Impala supports Active Directory Kerberos in Windows. There are two prerequisites for using Active Directory Kerberos in Windows:

- MIT Kerberos is not installed on the client Windows machine.
- The MIT Kerberos Hadoop realm has been configured to trust the Active Directory realm, according to Apache's documentation, so that users in the Active Directory realm can access services in the MIT Kerberos Hadoop realm.

Write-back

The Cloudera ODBC Connector for Apache Impala supports translation for the following syntax:

- INSERT
- CREATE
- DROP

The connector also supports translation for UPDATE and DELETE syntax, but only when querying Kudu tables while connected to an Impala server that is running Impala 2.7 or later.

If the statement contains non-standard SQL-92 syntax, then the connector is unable to translate the statement to SQL and instead falls back to using Impala SQL.

Security and Authentication

To protect data from unauthorized access, some Impala data stores require connections to be authenticated with user credentials or encrypted using the SSL protocol. The Cloudera ODBC Connector for Apache Impala provides full support for these authentication protocols.

Note: In this documentation, "SSL" refers to both TLS (Transport Layer Security) and SSL (Secure Sockets Layer). The connector supports TLS 1.0, 1.1, and 1.2. The SSL version used for the connection is the highest version that is supported by both the connector and the server.

The connector provides mechanisms that enable you to authenticate your connection using the Kerberos protocol, the OAuth 2.0 protocol, your Impala user name only, or your Impala user name and password. You must use the authentication mechanism that matches the security requirements of the Impala server. For information about determining the appropriate authentication mechanism to use

Features

based on the Impala server configuration, see Authentication Options. For detailed connector configuration instructions, see Configuring Authentication in Windows or Configuring Authentication on a Non-Windows Machine.

Additionally, the connector supports SSL connections with or without one-way authentication. If the server has an SSL-enabled socket, then you can configure the connector to connect to it.

It is recommended that you enable SSL whenever you connect to a server that is configured to support it. SSL encryption protects data and credentials when they are transferred over the network, and provides stronger security than authentication alone. For detailed configuration instructions, see Configuring SSL Verification in Windows or Configuring SSL Verification in a Non-Windows Machine.

Connector Configuration Options

Connector Configuration Options lists the configuration options available in the Cloudera ODBC Connector for Apache Impala alphabetically by field or button label. Options having only key names, that is, not appearing in the user interface of the connector, are listed alphabetically by key name.

When creating or configuring a connection from a Windows machine, the fields and buttons are available in the following dialog boxes:

- Cloudera ODBC Connector for Apache Impala DSN Setup
- Advanced Options
- OAuth Options
- Keytab Options
- Server Side Properties
- SSL Options

When using a connection string, configuring connector-wide settings, or configuring a connection from a non-Windows machine, use the key names provided.

Note:

Settings in the connection string take precedence over settings in the DSN, and settings in the DSN take precedence over connector-wide settings.

Configuration Options Appearing in the User Interface

The following configuration options are accessible via the Windows user interface for the Cloudera ODBC Connector for Apache Impala, or via the key name when using a connection string, configuring connector-wide settings, or configuring a connection from a Linux/macOS/AIX machine:

- Audience
- Allow Common Name Host Name Mismatch
- Allow Self-Signed Server Certificate
- Async Exec Poll Interval
- Access Token
- Authentication Flow

- Proxy Host
- Proxy Password
- Proxy Port
- Proxy Username
- Realm
- Restrict Metadata with Current Schema

Connector Configuration Options

- Authorization Endpoint
- Canonicalize Principal FQDN
- CheckCertificate Revocation
- Client ID
- Client Secret
- Convert Key Name to Lower Case
- Database
- Default Keytab File
- Delegation UID
- Enable Auto Reconnect
- Enable Query Retry
- Enable Token Cache
- Enable Routing To Same Coordinator
 For Cached SAML Auth Cookie
- Enable SAML Auth Cookie Caching
- Enable SSL
- Host
- Host FQDN
- HTTP Path
- Ignore SQL_DRIVER_NOPROMPT
- Ignore Transactions
- JWTString
- Log Level
- Log Path
- Max File Size

- Result Set Cache Size
- Retry Interval
- Rows Fetched Per Block
- Service Name
- Socket Timeout
- String Column Length
- TokenCachePassPhrase
- Token Endpoint
- TokenRenewLimit
- Transport Buffer Size
- Transport Mode
- Trusted Certificates
- UPN Keytab Mapping File
- Use Keytab
- Use Native Query
- Use Only SSPI
- Use Proxy
- Use Simple Authentication and Security Layer (SASL)
- Use SQL Unicode Types
- Use System Trust Store
- User Name

- Max Number Files
- **Maximum Retries**
- Mechanism
- Minimum TLS
- OAuth Scope
- Password
- Port

Access Token

The access token for authenticating the connection through the OAuth 2.0 protocol.

Note: In case of unixODBC, when the Auth AccessToken line length is longer than the maximum limit of 1000, add the following in your odbc.ini file:

In the ODBC section:

■ Auth AccessToken=(your access token)

In the DSN section:

- ConfigsFromFileDSN=Auth AccessToken
- FILEDSNPATH=(Full path of the odbc.ini file)
- Auth AccessToken=(your access token)

If you have multiple DSN configured in your odbc.ini file and each of them require a different Auth AccessToken, you can add the Auth AccessToken to the ODBC section of a different ini file, and configure the FILEDSNPATH in your DSN to point to this inifile.

Key Name	Default Value	Required
Auth_AccessToken	None	Yes, if the authentication mechanism is OAuth 2.0 and the work flow is Token Passthrough (0).

Allow Common Name Host Name Mismatch

This option specifies whether a CA-issued SSL certificate name must match the host name of the Impala server.

Note: The key for this option used to be CAIssuedCertNamesMismatch, and is still recognized by the connector under that key. If both keys are defined, AllowHostNameCNMismatch will take precedence.

This setting is applicable only when SSL is enabled.

- Enabled (1): The connector allows a CA-issued SSL certificate name to not match the host name of the Impala server.
- Disabled (0): The CA-issued SSL certificate name must match the host name of the Impala server.

Key Name	Default Value	Required
AllowHostNameCNMismatch	Clear (0)	No

Allow Self-Signed Server Certificate

This option specifies whether the connector allows a connection to anImpala server that uses a self-signed certificate.

- Enabled (1): The connector authenticates the Impala server even if the server is using a self-signed certificate.
- Disabled (0): The connector does not allow self-signed certificates from the server.

Note: This setting is applicable only when SSL is enabled.

Key Name	Default Value	Required
AllowSelfSignedServer Cert	Clear (0)	No

Async Exec Poll Interval

The time in milliseconds between each poll for the query execution status.

"Asynchronous execution" refers to the fact that the RPC call used to execute a query against Impala is asynchronous. It does not mean that ODBC asynchronous operations are supported.

Key Name	Default Value	Required
AsyncExecPollInterval	10	No

Audience

The audience used in OAuth connections.

Key Name	Default Value	Required
Auth_Audience	None	No

Authorization Endpoint

The Authorization endpoint used in OAuth connections.

Key Name	Default Value	Required
OAuth2AuthorizationEndPoint	None	No

Authentication Flow

This option specifies the type of OAuth authentication flow that the connector uses when the Mechanism option is set to OAuth 2.0 or SAML_2.0 (or when AuthMech is set to OAuth 2.0 or SAML 2.0). When SAML 2.0 is selected, only Browser is supported for this option.

When this option is set to Token Passthrough (0), the connector uses the access token specified by the Access Token (Auth AccessToken) option to authenticate the connection to the server. For more information, see Access Token.

When this option is set to Client Credentials (1), the connector uses the client credentials to authenticate the connection to the server.

When this option is set to Browser Based Authorization Code (2), the connector uses the browser based authorization code flow to authenticate the connection to the server.

Key Name	Default Value	Required
_	Token Passthrough (0) for OAuth 2.0 and Browser for SAML_2.0	No

Canonicalize Principal FQDN

This option specifies whether the Kerberos layer canonicalizes the host FQDN in the server's service principal name.

- Enabled (1): The Kerberos layer canonicalizes the host FQDN in the server's service principal name.
- Disabled (0): The Kerberos layer does not canonicalize the host FQDN in the server's service principal name.

Note: This option only affects MIT Kerberos, and is ignored when using Active Directory Kerberos. It can only be disabled if the Kerberos Realm or KrbRealm key is specified.

Key Name	Default Value	Required
ServicePrincipal Canonicalization	Selected (1)	No

CheckCertificate Revocation

This option specifies whether the connector checks to see if a certificate has been revoked while retrieving a certificate chain from the Windows Trust Store.

This option is only applicable if you are using a CA certificate from the Windows Trust Store (see Use System Trust Store).

- Enabled (1): The connector checks for certificate revocation while retrieving a certificate chain from the Windows Trust Store.
- Disabled (0): The connector does not check for certificate revocation while retrieving a certificate chain from the Windows Trust Store.

Note:

- This option is disabled when the AllowSelfSignedServerCert property is set to 1.
- This option is only available in Windows.

Key Name	Default Value	Required
CheckCertRevocation	Selected (1)	No

Client ID

The client ID used in OAuth connections.

Key Name	Default Value	Required
Auth_Client_ID	None	No

Client Secret

The client secret associated with the client ID used in OAuth connections.

Key Name	Default Value	Required
Auth_Client_Secret	None	No

Convert Key Name to Lower Case

This option specifies whether the connector converts server-side property key names to all lower-case characters.

- Enabled (1): The connector converts server-side property key names to all lower-case characters.
- Disabled (0): The connector does not modify the server-side property key names.

Key Name	Default Value	Required
LCaseSspKeyName	Selected (1)	No

Database

The name of the database schema to use when a schema is not explicitly specified in a guery. You can still issue queries on other schemas by explicitly specifying the schema in the query.

Note: To inspect your databases and determine the appropriate schema to use, at the Impala command prompt, type show databases.

Key Name	Default Value	Required
Schema	default	No

Default Keytab File

The full path to the keytab file that the connector uses to obtain the ticket for Kerberos authentication.

Note:

- This option is applicable only when the authentication mechanism is set to Kerberos (AuthMech=Kerberos) and the Use Keytab option is enabled (UseKeytab=1).
- If the UPN Keytab Mapping File option (the UPNKeytabMappingFile key) is set to a JSON file with a valid mapping to a keytab, then that keytab takes precedence.

If you do not set this option but the Use Keytab option is enabled (UseKeytab=1), then the MIT Kerberos library will search for a keytab using the following search order:

- The file specified by the KRB5 KTNAME environment variable.
- The default keytab name setting in the [libdefaults] section of the Kerberos configuration file (krb5.conf/krb5.ini).
- The default keytab file specified in the MIT Kerberos library. Typically, the default file is C:\Windows\krb5kt for Windows platforms and /etc/krb5.keytab for non-Windows platforms.

Key Name	Default Value	Required
DefaultKeytabFile	None	No

Delegation UID

If a value is specified for this setting, the connector delegates all operations against Impala to the specified user, rather than to the authenticated user for the connection.

Key Name	Default Value	Required
DelegationUID	None	No

Enable Auto Reconnect

This option specifies whether the connector attempts to automatically reconnect to the server when a communication link error occurs.

- Enabled (1): The connector attempts to reconnect.
- Disabled (0): The connector does not attempt to reconnect.

Key Name	Default Value	Required
AutoReconnect	Selected (1)	Yes

Enable Routing To Same Coordinator For Cached SAML Auth Cookie

This option specifies whether the connector uses the cached SAML auth cookie to route to the same coordinator in subsequent connections.

- Enabled (1): The connector uses the cached SAML auth cookie to route to the same coordinator in subsequent connections.
- Disabled (0): The connector does not use the cached SAML auth cookie to route to the same coordinator in subsequent connections.

Note:

- This property is available only in Windows.
- This property is active only when the configuration option Enable SAML Auth Cookie Caching is enabled.
- This property addresses issues where SAML auth cookie caching may fail in an Impala cluster with active-active coordinators. If the cluster uses a coordinator-specific auth cookie mechanism, the cached SAML auth cookie is valid only for the issuing coordinator. When the cached cookie happens to be routed to a different coordinator, authentication fails. In this case, enabling this configuration ensures consistent routing to the correct coordinator. If the cluster uses a shared auth cookie mechanism across coordinators, the cached SAML auth cookie remains valid across all coordinators. In this case, disabling this configuration is recommended to avoid unnecessary routing and improve load balancing.

Key Name	Default Value	Required
EnableRoutingToSameCoordinatorForCachedSamlAuthCookie	Clear	No

Enable Query Retry

This option specifies whether the connector automatically retries queries that are sent to the server but fail.

- Enabled (1): The connector retries failed queries.
- Disabled (0): The connector only submits each query once.

Query retry settings are configured through the following options:

- **Maximum Retries**
- Result Set Cache Size
- **Retry Interval**
- GlobalResultSetCache

Key Name	Default Value	Required
EnableQueryRetry	Clear (0)	No

Enable SAML Auth Cookie Caching

This option specifies whether the connector uses the auth cookie when using SAML SSO authentication.

- Enabled (1):The connector caches the authorization cookie and does not open a new browser every time while establishing a new connection using SAML SSO authentication.
- Disabled (0): The connector does not cache the authorization cookie and opens a new browser every time while establishing a new connection using SAML SSO authentication.

Note:

- This property is available only in Windows.
- When this configuration is enabled, the Username and Password configurations are optional.
- The Username and Password can be optionally used as parts of the key for uniquely identifying the cache entries in the cache.
- The Password is used to encrypt the key so that the key is not stored in plain text in the cache file.

Key Name	Default Value	Required
EnableSamlCookieCaching	Clear (0)	No

Enable SSL

This option specifies whether the client uses an SSL encrypted connection to communicate with the Impala server.

- Enabled (1): The client communicates with the Impala server using SSL.
- Disabled (0): SSL is disabled.

SSL is configured independently of authentication. When authentication and SSL are both enabled, the connector performs the specified authentication method over an SSL connection.

Key Name	Default Value	Required
SSL	Clear (0)	No

Enable Token Cache

This option specifies whether the connector enables or disables token cache for OAuth2 Browser Based authentication.

- Enabled (1): The connector enables the token cache for OAuth2 Browser Based authentication.
- Disabled (0): The connector disables the token cache for OAuth2 Browser Based authentication.

Key Name	Default Value	Required
EnableTokenCache	Enabled (1)	No

HTTP Path

The partial URL corresponding to the Impala server.

The connector forms the HTTP address to connect to by appending the HTTP Path value to the host and port specified in the DSN or connection string. For example, to connect to the HTTP address http://localhost:21050/gateway/sandbox/impala/version, you would set HTTP Path to /gateway/sandbox/impala/version.

Key Name	Default Value	Required
HTTPPath	None	No

Host

The IP address or host name of the Impala server.

Key Name	Default Value	Required
Host (or Server)	None	Yes

Host FQDN

The fully qualified domain name of the Impala host.

When the value of Host FQDN is HOST, the connector uses the Impala server host name as the fully qualified domain name for Kerberos authentication.

Key Name	Default Value	Required
KrbFQDN	_HOST	No

Ignore Transactions

This option specifies whether the connector should simulate transactions, or return an error.

- Enabled (1): The connector simulates transactions, enabling queries that contain transaction. statements to be run successfully. The transactions are not executed.
- Disabled (0): The connector returns an error if it attempts to run a query that contains transaction statements.

Note:

ODBC does not support transaction statements, so they cannot be executed.

Key Name	Default Value	Required
IgnoreTransactions	Clear (0)	No

Ignore SQL_DRIVER_NOPROMPT

This option specifies whether the connector displays a web browser when the application makes a SQLDriverConnect API call with a SQL_DRIVER_NOPROMPT flag to the connector.

- Enabled (true): The connector displays the web browser used to complete the browser based authentication flow even when SQL_DRIVER_NOPROMPT is passed.
- Disabled (false): The connector does not display a web browser.

Note:

- SSOIgnoreDriverNoPrompt configuration affects only the SAML SSO authentication.
- For other authentication mechanisms, SQL_DRIVER_NOPROMPT parameter works as expected.

Key Name	Default Value	Required
SSOlgnoreDriverNoPrompt	true	No

JWTString

The JSON Web Token used to access the server.

Note:

This option is only available when using \mathtt{JWT} as the authentication mechanism.

Note:

When using unixODBC:

When the JWTString line length is longer than the maximum limit of 1000, add the following in your odbc.ini file:

In the ODBC section:

JWTString=(your JWT token)

In the DSN section:

- FILEDSNPATH=(Full path of the odbc.ini file)
- ConfigsFromFileDSN=JWTString
- JWTString=(your JWT token)

If you have multiple DSN configured in your odbc.ini file and each of them require a different JWTString, you can add the JWTString to the ODBC section of a different ini file, and configure the FILEDSNPATH in your DSN to point to this inifile.

Key Name	Default Value	Required
JWTString	INONE	Yes, if the authentication mechanism is JWT.

Log Level

Use this property to enable or disable logging in the connector and to specify the amount of detail included in log files.

Important:

- Only enable logging long enough to capture an issue. Logging decreases performance and can consume a large quantity of disk space.
- When logging with connection strings and DSNs, this option only applies to perconnection logs.

Set the property to one of the following values:

- OFF (0): Disable all logging.
- FATAL (1): Logs severe error events that lead the connector to abort.
- ERROR (2): Logs error events that might allow the connector to continue running.
- WARNING (3): Logs events that might result in an error if action is not taken.
- INFO (4): Logs general information that describes the progress of the connector.
- DEBUG (5): Logs detailed information that is useful for debugging the connector.
- TRACE (6): Logs all connector activity.

When logging is enabled, the connector produces the following log files at the location you specify in the Log Path (LogPath) property:

- A clouderaodbcdriverforimpala.log file that logs connector activity that is not specific to a connection.
- A clouderaodbcdriverforimpala connection [Number].log file for each connection made to the database, where [Number] is a number that identifies each log file. This file logs connector activity that is specific to the connection.

If you enable the UseLogPrefix connection property, the connector prefixes the log file name with the user name associated with the connection and the process ID of the application through which the connection is made. For more information, see UseLogPrefix.

Key Name	Default Value	Required
LogLevel	OFF (0)	No

Log Path

The full path to the folder where the connector saves log files when logging is enabled.

Important: When logging with connection strings and DSNs, this option only applies to perconnection logs.

Key Name	Default Value	Required
LogPath	None	Yes, if logging is enabled.

Max File Size

The maximum size of each log file in bytes. After the maximum file size is reached, the connector creates a new file and continues logging.

If this property is set using the Windows UI, the entered value is converted from megabytes (MB) to bytes before being set.

Important: When logging with connection strings and DSNs, this option only applies to perconnection logs.

Key Name	Default Value	Required
LogFileSize	20971520	No

Max Number Files

The maximum number of log files to keep. After the maximum number of log files is reached, each time an additional file is created, the connector deletes the oldest log file.

Important: When logging with connection strings and DSNs, this option only applies to perconnection logs.

Key Name	Default Value	Required
LogFileCount	50	No

Maximum Retries

The maximum number of times that the connector retries a failed query, when query retry is enabled.

Also see Enable Query Retry.

Key Name	Default Value	Required
MaxNumQueryRetries	5	No

Mechanism

The authentication mechanism to use.

Select one of the following settings, or set the key to the authentication name:

- No Authentication (No Authentication or 0)
- Kerberos (Kerberos or 1)
- SASL User Name (SASL User Name or 2)
- User Name And Password (User Name and Password or 3)
- JWT (JWT or 8)
- OAuth 2.0 (OAuth 2.0 or 9)
- **SAML_2.0** (SAML 2.0)
- Note: The AuthMech property now uses the authentication mechanism's name instead of the corresponding numbers. The connector continues to recognize the corresponding numbers (0, 1, 2, 3, and 8) for backwards compatibility.\
- Note: For connector version 2.7.1. and earlier, when using JWT to connect to an Impala virtual warehouse cluster with active-active coordinators, the connector may return a 401 error for the first operation after the connection is established. As a workaround, add the following configuration to the DSN or connector string: AuthorizationHeaderReplacementCookie=impala.auth

Key Name	Default Value	Required
	No Authentication (No Authentication or 0)	No

Minimum TLS

The minimum version of TLS/SSL that the connector allows the data store to use for encrypting connections. For example, if TLS 1.1 is specified, TLS 1.0 cannot be used to encrypt connections.

- TLS 1.0 (1.0): The connection must use at least TLS 1.0.
- TLS 1.1 (1.1): The connection must use at least TLS 1.1.
- TLS 1.2 (1.2): The connection must use at least TLS 1.2.

Key Name	Default Value	Required
Min_TLS	TLS 1.2 (1.2)	No

OAuth Scope

The scope used in the OAuth 2.0 connection.

Key Name	Default Value	Required
Auth_Scope	None	No

Password

The password corresponding to the user name that you provided in the User Name field (the UID key).

Key Name	Default Value	Required
PWD	None	Yes, if the authentication mechanism is User Name And Password (User Name and Password).

Port

The number of the TCP port that the Impala server uses to listen for client connections.

Key Name	Default Value	Required
Port	21050	Yes

Proxy Host

The host name or IP address of a proxy server that you want to connect through.

Key Name	Default Value	Required
ProxyHost	Ivone	Yes, if connecting through a proxy server.

Proxy Port

The number of the port that the proxy server uses to listen for client connections.

Key Name	Default Value	Required
ProxyPort	Inone	Yes, if connecting through a proxy server.

Proxy Password

The password that you use to access the proxy server.

Key Name	Default Value	Required
ProxyPWD		Yes, if connecting to a proxy server that requires authentication.

Proxy Username

The user name that you use to access the proxy server.

Key Name	Default Value	Required
ProxyUID	None	Yes, if connecting to a proxy server that requires authentication.

Realm

The realm of the Impala host.

If your Kerberos configuration already defines the realm of the Impala host as the default realm, then you do not need to configure this option.

Key Name	Default Value	Required
KrbRealm	NULL	No

Restrict Metadata with Current Schema

This option specifies whether the connector should restrict catalog function results to tables and views in the current schema if a catalog function call is made without specifying a schema, or if the schema is specified as the wildcard character %.

Note:

Restricting results to the tables and views in the current schema may improve the performance of catalog calls that do not specify a schema.

- Enabled (1): The connector restricts catalog function results to the current schema if a schema is not specified.
- Disabled (0): The connector does not restrict catalog function results to the current schema if a schema is not specified.

Key Name	Default Value	Required
CurrentSchema RestrictedMetadata	Clear (0)	No

Result Set Cache Size

The maximum amount of memory that the result set cache for the current connection can occupy. Values must be specified in: B (bytes), KB (kilobytes), MB (megabytes), or GB (gigabytes).

When query retries are enabled, the connector temporarily caches result sets. For more information about this feature, see Enable Query Retry.

For information about setting a maximum total cache size for all concurrent connections, see GlobalResultSetCache.

Key Name	Default Value	Required
ResultSetCacheSize	20MB	No

Retry Interval

The amount of time that the connector waits between query retry attempts, when query retry is enabled. Values can be specified in S (seconds) or MS (milliseconds).

Also see Enable Query Retry.

Key Name	Default Value	Required
QueryRetryInterval	5S	No

Rows Fetched Per Block

The maximum number of rows that a query returns at a time.

Valid values for this setting include any positive 32-bit integer. However, testing has shown that performance gains are marginal beyond the default value of 10000 rows.

Key Name	Default Value	Required
RowsFetchedPerBlock	10000	No

Service Name

The Kerberos service principal name of the Impala server.

Key Name	Default Value	Required
KrbServiceName	impala	No

Socket Timeout

The number of seconds that the TCP socket waits for a response from the server before timing out the request and returning an error message.

When this option is set to 0, the TCP socket does not time out any requests.

Key Name	Default Value	Required
SocketTimeout	30	No

String Column Length

The maximum number of characters that can be contained in STRING columns.

Key Name	Default Value	Required
StringColumnLength	32767	No

TokenCachePassPhrase

The password used to protect the token cache.

Note: This option is required only on non-Windows platform.

Key Name	Default Value	Required
TokenCachePassPhrase	None	Yes

Token Endpoint

The token endpoint used in OAuth connections.

Key Name	Default Value	Required
OAuth2TokenEndPoint	None	No

TokenRenewLimit

TokenRenewLimit sets the threshold (in minutes) for renewing the access token when its remaining lifetime is less than or equal to this value.

Key Name	Default Value	Required
TokenRenewLimit	0	No

Transport Buffer Size

The number of bytes to reserve in memory for buffering unencrypted data from the network.

In most circumstances, the default value of 1000 bytes is optimal.

Key Name	Default Value	Required
TSaslTransportBufSize	1000	No

Transport Mode

The transport protocol to use in the Thrift layer.

Select one of the following settings, or set the key to the number or string corresponding to the desired setting:

- Binary (0 or binary)
- SASL (1 or sasl)
- HTTP (2 or http)
- Note: For information about how to determine which Thrift transport protocols your Impala server supports, see Mechanism.
- Note:
 - If this property is specified, it takes precedence over the Use SASL property (UseSASL).
 - If this property is not specified and the Use SASL property is specified, the Use SASL property takes precedence over the default value of this property.

For more information, see Use Simple Authentication and Security Layer (SASL).

Key Name	Default Value	Required
TransportMode	Binary (0) if using No Authentication, otherwise SASL (1).	No

Trusted Certificates

The full path of the . pem file containing trusted CA certificates, for verifying the server when using SSL.

If this option is not set, then the connector defaults to using the trusted CA certificates . pem file installed by the connector. To use the trusted CA certificates in the .pem file, set the UseSystemTrustStore property to 0 or clear the Use System Trust Store check box in the SSL Options dialog.

Important:

If you are connecting from a Windows machine and the Use System Trust Store option is enabled, the connector uses the certificates from the Windows trust store instead of your specified .pem file.

For more information, see Use System Trust Store.

Key Name	Default Value	Required
TrustedCerts	The cacerts.pem file in the \lib subfolder within the connector's installation directory. The exact file path varies depending on the version of the connector that is installed. For example, the path for the Windows connector is different from the path for the macOS connector.	No

UPN Keytab Mapping File

The full path to a JSON file that maps your Impala user name to a Kerberos user principal name and a keytab file.

Note:

This option is applicable only when the authentication mechanism is set to Kerberos (AuthMech=Kerberos) and the Use Keytab option is enabled (UseKeytab=1).

The mapping in the JSON file must be written using the following schema, where [UserName] is the Impala user name, [KerberosUPN] is the Kerberos user principal name, and [Keytab] is the full path to the keytab file:

```
{
       "[UserName]": {
              "principal": "[KerberosUPN]",
              "keytab": "[Keytab]"
       },
... }
```

For example, the following file maps the Impala user name cloudera to the cloudera@CLOUDERA Kerberos user principal name and the C:\Temp\cloudera.keytab file:

```
{
      "cloudera": {
             "principal": "cloudera@CLOUDERA",
             "keytab": "C:\Temp\cloudera.keytab"
      },
... }
```

If parts of the mapping are invalid or not defined, then the following occurs:

- If the mapping file fails to specify a Kerberos user principal name, then the connector uses the Impala user name as the Kerberos user principal name.
- If the mapping file fails to specify a keytab file, then the connector uses the keytab file that is specified in the Default Keytab File setting.
- If the entire mapping file is invalid or not defined, then the connector does both of the actions described above.

Key Name	Default Value	Required
UPNKeytabMappingFile	None	No

Use Keytab

This option specifies whether the connector obtains the ticket for Kerberos authentication by using a keytab.

- Enabled (1): The connector uses a keytab to obtain a ticket before authenticating the connection using Kerberos.
- Disabled (0): The connector does not attempt to obtain the Kerberos ticket, and assumes that a valid ticket is already available in the credentials cache.

Note:

This option is applicable only when the authentication mechanism is set to Kerberos (AuthMech=Kerberos).

If you enable this option but do not set the Default Keytab File option (the DefaultKeytabFile key), then the MIT Kerberos library will search for a keytab file using the following search order:

- 1. The file specified by the KRB5 KTNAME environment variable.
- 2. The default keytab name setting in the [libdefaults] section of the Kerberos configuration file (krb5.conf/krb5.ini).
- 3. The default keytab file specified in the MIT Kerberos library. Typically, the default file is C:\Windows\krb5kt for Windows platforms.

Key Name	Default Value	Required
UseKeytab	Clear (0)	No

Use Native Query

This option specifies whether the connector uses native Impala SQL queries, or converts the queries emitted by an application into an equivalent form in Impala SQL. If the application is Impala-aware and already emits Impala SQL, then enable this option to avoid the extra overhead of guery transformation.

- Enabled (1): The connector does not transform the queries emitted by an application, and executes Impala SQL queries directly.
- Disabled (0): The connector transforms the gueries emitted by an application and converts them into an equivalent form in Impala SQL.

Important:

When this option is enabled, the connector cannot execute parameterized queries.

Key Name	Default Value	Required
UseNativeQuery	Clear (0)	No

Use Only SSPI

This option specifies how the connector handles Kerberos authentication: either with the SSPI plugin or with MIT Kerberos.

- Enable For This DSN (1 in the DSN entry in the registry): The connector handles Kerberos authentication in the DSN connection by using the SSPI plugin instead of MIT Kerberos by default.
- Enable For DSN-less Connections (1 in the connector configuration section of the registry): The connector handles Kerberos authentication in DSN-less connections by using the SSPI plugin instead of MIT Kerberos by default.

If you want all connections that use the Cloudera ODBC Connector for Apache Impala to use the SSPI plugin by default, then enable Use Only SSPI for both DSN and DSN-less connections.

Disabled (0): The connector uses MIT Kerberos to handle Kerberos authentication, and only uses the SSPI plugin if the GSSAPI library is not available.

Important: This option is only available in Windows.

Key Name	Default Value	Required
UseOnlySSPI	Clear (0)	No

Use Proxy

This option specifies whether the connector uses a proxy server to connect to the data store.

- Enabled (1): The connector connects to a proxy server based on the information provided in the Proxy Host, Proxy Port, Proxy Username, and Proxy Password fields or the ProxyHost, ProxyPort, ProxyUID, and ProxyPWD keys.
- Disabled (0): The connector connects directly to the Impala server.

Key Name	Default Value	Required
UseProxy	Clear (0)	No

Use Simple Authentication and Security Layer (SASL)

This option specifies whether the connector uses SASL to handle authentication.

- Enabled (1): The connector uses SASL to handle authentication.
- Disabled (0): The connector does not use SASL.

This option is configurable only when you are using the User Name And Password authentication mechanism. If the connector is configured to use the other authentication mechanisms, then it uses the default setting for the Use Simple Authentication and Security Layer (SASL) option.

Note:

- If the Transport Mode property (TransportMode) is specified, it takes precedence over this property.
- If the Transport Mode property is not specified and this property is specified, this property takes precedence over the default value of Transport Mode.

For more information, see Transport Mode.

Key Name	Default Value	Required
	0 if using No Authentication.	
UseSASL	1 if using User Name And Password or Kerberos or SASL User Name authentication.	No

Use SQL Unicode Types

This option specifies the SQL types to be returned for string data types.

- Enabled (1): The connector returns SQL_WVARCHAR for STRING and VARCHAR columns, and returns SQL_WCHAR for CHAR columns.
- Disabled (0): The connector returns SQL_VARCHAR for STRING and VARCHAR columns, and returns SQL_CHAR for CHAR columns.

Key Name	Default Value	Required
UseSQLUnicodeTypes	Clear (0)	No

Use System Trust Store

This option specifies whether to use a CA certificate from the system trust store, or from a specified .pem file.

- Enabled (1): The connector verifies the connection using a certificate in the system trust store.
- Disabled (0): The connector verifies the connection using a specified . pem file. For information about specifying a .pem file, see Trusted Certificates.

Important:

If you are connecting from a Windows machine and you want to specify a . pem file containing trusted CA certificates, this option must be disabled. For more information, see Trusted Certificates.

Note: This option is only available in Windows.

Key Name	Default Value	Required
UseSystemTrustStore	Clear (0)	No

User Name

The user name that you use to access the Impala server.

Key Name	Default Value	Required
UID	For User Name (2) authentication only, the default value is anonymous	Yes, if the authentication mechanism is User Name And Password (User Name and Password). No, if the authentication mechanism is SASL User Name (SASL User Name).

Configuration Options Having Only Key Names

The following configuration options do not appear in the Windows user interface for the Cloudera ODBC Connector for Apache Impala. They are accessible only when you use a connection string, configure connector-wide settings, or configure a connection from a Linux/macOS/AIX machine:

- ConfigsFromFileDSN
- DelegationUserIDCase
- DisableOptimizedEncodingConverter
- EnableMultiSocketFetch
- GlobalResultSetCache

- **HTTPAuthCookies**
- http.header.
- MaxCatalogNameLen
- MaxColumnNameLen
- MaxSchemaNameLen
- MaxTableNameLen
- MaxNumMultiSocketFetchHandlers
- MaxNumMultiSocketFetchRowsetPerOperation
- SSP_
- SSOWebServerTimeout

The UseLogPrefix property must be configured as a Windows Registry key value, or as a connectorwide property in the cloudera.impalaodbc.ini file for macOS or Linux.

UseLogPrefix

ConfigsFromFileDSN

A comma-separated list of configuration names that the connector reads from the DSN file.

The connector only attempts to read the configuration values from a file DSN if the following conditions are met:

- The FILEDSN configuration is passed in via the connection string.
- The configuration key-value pairs must be inside the ODBC section in the DSN file.
- The ConfigsFromFileDSN configuration is either passed in via the connection string or via the file DSN, and the value of the ConfigsFromFileDSN configuration must contain the names, comma-separated, of the configurations to read from the DSN file.
- The value of the FILEDSN configuration is a valid directory path pointing to the location of the file DSN.

Important:

In some cases, the configuration of FILEDSN is removed from the connection string. In this case, add a FILEDSNPATH configuration to the connection string with the same value that is passed in for the FILEDSN configuration.

Key Name	Default Value	Required
ConfigsFromFileDSN	None	No

DelegationUserIDCase

This option specifies whether the connector changes the Delegation UID (or DelegationUID) value to all upper-case or all lower-case. The following values are supported:

- Upper: Change the delegated user name to all upper-case.
- Lower: Change the delegated user name to all lower-case.
- Unchanged: Do not modify the delegated user name.

For more information about delegating a user name, see Delegation UID.

Key Name	Default Value	Required
DelegationUserIDCase	Unchanged	No

DisableOptimizedEncodingConverter

This connector-wide option controls which data encoding converter the connector uses.

Note:

Enabling this option may result in decreased performance.

- true: The connector uses a standard ICU converter.
- false: The connector uses an optimized converter.

Important:

This option applies to every connection that uses the Cloudera ODBC Connector for Apache Impala. For more information, see Setting Connector-Wide Configuration Options in Windows or Setting Connector-Wide Configuration Options on a Non-Windows Machine.

Key Name	Default Value	Required
DisableOptimizedEncodingConverter	false	No

Driver

In Windows, the name of the installed connector for (ClouderaODBC Driver for Impala).

On other platforms, the name of the installed connector as specified in odbcinst.ini, or the absolute path of the connector shared object file.

Key Name	Default Value	Required
Driver	Cloudera Impala ODBC Driver for Impala when installed in Windows, or the	Yes

Key Name	Default Value	Required
	absolute path of the connector shared object file when installed on a non-Windows machine.	

EnableMultiSocketFetch

This properties specifies whether to enable the multi-socket fetch feature for the connection.

- 1: The connector enables multi-socket fetch.
- 0: The connector disables multi-socket fetch.

Note:

- The multi-socket fetch feature is currently not supported when using SAML 2.0 authentication or JWT authentication.
- The multi-socket fetch feature is currently not supported when connecting to an Impala Virtual Warehouse cluster with active-active coordinators.

Key Name	Default Value	Required
EnableMultiSocketFetch	0	No

GlobalResultSetCache

The maximum total amount of memory that can be occupied by result set caches across concurrent connections. Values must be specified in: B (bytes), KB (kilobytes), MB (megabytes), or GB (gigabytes).

For example, when this property is set to the default value of 200MB, if you have 3 concurrent Impala connections, the total amount of memory consumed by the 3 result set caches for those connections cannot exceed 200MB.

These result set caches are used only when query retries are enabled. For more information about this feature, see Enable Query Retry.

For information about setting a maximum cache size for the current connection only, see Result Set Cache Size.

Key Name	Default Value	Required
GlobalResultSetCache	200MB	No

HTTPAuthCookies

A comma-separated list of authentication cookies that are supported by the connector.

If cookie-based authentication is enabled in your server, the connector authenticates the connection once based on the provided authentication credentials. It then uses the cookie generated by the server for each subsequent request in the same connection.

Key Name	Default Value	Required
HTTPAuthCookies	impala.auth, JSESSIONID, KNOXSESSIONID,	No
IIIIFAUCIICOOKIES	impala.session.id	No

http.header.

Set a custom HTTP header by using the following syntax, where [HeaderKey] is the name of the header to set and [HeaderValue] is the value to assign to the header:

```
http.header.[HeaderKey]=[HeaderValue]
```

For example:

```
http.header.AUTHENTICATED USER=john
```

After the connector applies the header, the http.header, prefix is removed from the DSN entry, leaving an entry of [HeaderKey]=[HeaderValue]

The example above would create the following custom HTTP header:

```
AUTHENTICATED USER: john
```

Note: The http.header. prefix is case-sensitive. This option is applicable only when you are using HTTP as the Thrift transport protocol. For more information, see Transport Mode.

Key Name	Default Value	Required
http.header.	None	No

SSP

Set a server-side property by using the following syntax, where [SSPKey] is the name of the server-side property and [SSPValue] is the value for that property:

```
SSP [SSPKey]=[SSPValue]
```

For example:

```
SSP MEM LIMIT=100000000
```

```
SSP REQUEST POOL=myPool
```

Or, to set those properties in a connection string, type the following:

```
SSP_MEM_LIMIT={1000000000}; SSP_REQUEST_POOL={myPool}
```

After the connector applies the server-side property, the SSP_prefix is removed from the DSN entry, leaving an entry of [SSPKey]=[SSPValue].

Important:

This property is supported only for connections to Impala 2.0 or later. In earlier versions of Impala, the SET statement can only be executed from within the Impala shell.

Note: The SSP_prefix must be upper case. When setting a server-side property in a connection string, it is recommended that you enclose the value in braces ({ }) to make sure that special characters can be properly escaped.

Key Name	Default Value	Required
SSP_	None	No

SSOWebServerTimeout

The length of time, in seconds, for which the connector waits for a browser response before timing out. If set to 0, the connector waits for an indefinite amount of time.

Note:

If SQL_ATTR_LOGIN_TIMEOUT is set, SQL_ATTR_LOGIN_TIMEOUT takes precedence. The connector honors SQL_ATTR_LOGIN_TIMEOUT when using the SAML authentication workflow.

Key Name	Default Value	Required
SSOWebServerTimeout	120	No

MaxCatalogNameLen

The maximum number of characters that can be returned for catalog names. This option can be set to any integer from 0 to 65535, inclusive. To indicate that there is no maximum length or that the length is unknown, set this option to 0.

Key Name	Default Value	Required
MaxCatalogNameLen	0	No

MaxColumnNameLen

The maximum number of characters that can be returned for column names. This option can be set to any integer from 0 to 65535, inclusive. To indicate that there is no maximum length or that the length is unknown, set this option to 0.

Key Name	Default Value	Required
MaxColumnNameLen	0	No

MaxNumMultiSocketFetchHandlers

The maximum number of multi-socket fetch handlers for the connection.

Key Name	Default Value	Required
MaxNumMultiSocketFetchHandlers	5	No

MaxNumMultiSocketFetchRowsetPerOperation

The maximum number of row sets to buffer in memory for each operation.

Key Name	Default Value	Required
MaxNumMultiSocketFetchRowsetPerOperation	10	No

MaxSchemaNameLen

The maximum number of characters that can be returned for schema names. This option can be set to any integer from 0 to 65535, inclusive. To indicate that there is no maximum length or that the length is unknown, set this option to 0.

Key Name	Default Value	Required
MaxSchemaNameLen	256	No

MaxTableNameLen

The maximum number of characters that can be returned for table names. This option can be set to any integer from 0 to 65535, inclusive. To indicate that there is no maximum length or that the length is unknown, set this option to 0.

Key Name	Default Value	Required
MaxTableNameLen	0	No

UseLogPrefix

This option specifies whether the connector includes a prefix in the names of log files so that the files can be distinguished by user and application.

Set the property to one of the following values:

1: The connector prefixes log file names with the user name and process ID associated with the connection that is being logged.

Connector Configuration Options

For example, if you are connecting as a user named "jdoe" and using the connector in an application with process ID 7836, the generated log files would be named <code>jdoe_7836_clouderaodbcdriverforimpala.log</code> and <code>jdoe_7836_clouderaodbcdriverforimpala_connection_[Number].log</code>, where [Number] is a number that identifies each connection-specific log file.

• 0: The connector does not include the prefix in log file names.

To configure this option for the Windows connector, you create a value for it in one of the following registry keys:

- For a 32-bit connector installed on a 64-bit machine: HKEY_LOCAL_
 MACHINE\SOFTWARE\Wow6432Node\Cloudera\Cloudera ODBC Driver for Impala\Driver
- Otherwise: HKEY_LOCAL_MACHINE\SOFTWARE\Cloudera\Cloudera ODBC Driver for Impala\Driver

Use UseLogPrefix as the value name, and either 0 or 1 as the value data.

To configure this option for a non-Windows connector, you must use the cloudera.impalaodbc.ini file.

Key Name	Default Value	Required
UseLogPrefix	0	No

ODBC API Conformance Level

The following table lists the ODBC interfaces that the Cloudera ODBC Connector for Apache Impala implements and the ODBC compliance level of each interface.

ODBC compliance levels are Core, Level 1, and Level 2. These compliance levels are defined in the ODBC Specification published with the Interface SDK from Microsoft.

Interfaces include both the Unicode and non-Unicode versions. For more information, see "Unicode Function Arguments" in the *ODBC Programmer's Reference*: http://msdn.microsoft.com/en-us/library/ms716246%28VS.85%29.aspx.

Conformance Level	INTERFACES	Conformance Level	INTERFACES
Core	SQLAllocHandle	Core	SQLGetStmtAttr
Core	SQLBindCol	Core	SQLGetTypeInfo
Core	SQLBindParameter	Core	SQLNativeSql
Core	SQLCancel	Core	SQLNumParams
Core	SQLCloseCursor	Core	SQLNumResultCols
Core	SQLColAttribute	Core	SQLParamData
Core	SQLColumns	Core	SQLPrepare
Core	SQLConnect	Core	SQLPutData
Core	SQLCopyDesc	Core	SQLRowCount
Core	SQLDescribeCol	Core	SQLSetConnectAttr
Core	SQLDisconnect	Core	SQLSetCursorName
